26th UEG Week 2018

Vienna, Austria, October 2018

Accepted abstracts available online at:
https://www.ueg.eu/publications/abstractbook
www.ueg.eu/education/library
http://journals.sagepub.com/home/uega

Disclaimer: United European Gastroenterology (UEG) is not responsible for errors or omissions in the abstracts. This abstract book was finalised on September 14, 2018, any changes received after this date have not been incorporated. Changes to presenters received after July 13 have been included in the online version of the programme and can be obtained at: www.ueg.eu/education/library.

Disclosure Policy: UEG is committed to ensuring scientific rigour and objectivity in all of its educational activities. These include all aspects of the educational programme at UEG Week including those that are directly and jointly sponsored activities.

All presenters, whether invited Faculty or abstract presenters, are required to disclose to those organising and attending meetings any relevant financial or other relationship that may lead to a potential bias. UEG reserves the right to review the information disclosed for potential conflicts of interest. Please note that the sole responsibility for the content of each presentation lies with the presenting author.

The UEG Scientific Committee requires all presenters to disclose any financial relationship with or any advisory role in the Biomedical Industry and the Biomedical Technology Industry during the past two years. These and any other potential conflicts of interest should be disclosed during introductory comments to the presentation. Invited speakers and oral abstract presenters are requested to disclose potential conflicts of interest on a PowerPoint slide to be shown immediately at the beginning of the presentation. Poster presenters are requested to disclose potential conflicts of interest at the bottom of their poster.

Conflicts of interest may exist through a financial relationship or when the individual has the opportunity to influence the content of a presentation, and can involve grants, honoraria, shares, paid positions on advisory boards, etc. Conflicts of interest are frequent and expected, and do not preclude an individual from giving a presentation providing the conflict is disclosed. If there is any doubt about the relevance of a potential conflict of interest UEG requires all presenters to err on the safe side and to disclose it.
Aims and scope
Launched in 2013, United European Gastroenterology Journal is the official Journal of United European Gastroenterology (UEG), a professional non-profit organisation combining all the leading European societies concerned with digestive disease. UEG’s member societies represent over 22,000 specialists working across medicine, surgery, paediatrics, GI oncology and endoscopy, which makes UEG a unique platform for collaboration and the exchange of knowledge.

United European Gastroenterology Journal provides an international forum for research in gastroenterology, publishing original articles which describe basic research, translational and clinical studies of interest to gastroenterologists and researchers in related fields. Articles from across all fields of gastroenterology are be welcomed by the Editor-in-Chief, including luminal, liver and pancreatic diseases, gastrointestinal surgery, gastrointestinal oncology, paediatric gastroenterology and nutrition as well as endoscopy.

Published article types include original research, reviews, guidelines papers and news items. The journal is a member of the Committee on Publication Ethics (COPE).

2018 annual subscription rates
United European Gastroenterology Journal ISSN: 2050-6406 (print) 2050-6414 (online) is published in February, April, June, August, October and December by SAGE Publications (London, Thousand Oaks, CA, New Delhi, Singapore, Washington DC and Melbourne).

Annual subscription (2018) including postage: Institutional Rate (combined print and electronic) £829/US$1534. Note VAT might be applicable at the appropriate local rate. Visit sagepublishing.com for more details. To activate your subscription (institutions only) visit online.sagepub.com online. Abstracts, tables of contents and contents alerts are available on this site free of charge for all. Student discounts, single issue rates and advertising details are available from SAGE Publications Ltd, 1 Oliver’s Yard, 55 City Road, London EC1Y 1SP, UK, tel. +44 (0)20 7324 8500, email: subscriptions@sagepub.co.uk and in North America, SAGE Publications Inc, PO Box 5096, Thousand Oaks, CA 91320, USA.

Frank Żerbib, MD, PhD, Professor of Gastroenterology, Specialized in motility disorders and reflux disease, Bordeaux University Hospital, France
PH Zhou, MD, PhD, Associate Professor of General Surgery, Endoscopy Center Zhongsgan Hospital, Fudan University, Shanghai, China
Letter of Thanks for UEG Week 2018 Reviewers

Dear Colleagues,

On behalf of the UEG Scientific Committee, I would like to take this opportunity to thank you most sincerely for your contribution as an abstract reviewer for the original programme of UEG Week Vienna 2018.

The abstract reviewing process has been again very important this year with a number of innovations introduced to improve especially the poster abstract presentations.

I know just how much time and effort reviewing abstracts takes, but without your expertise we would not have the quality that I believe we have achieved in the free paper and poster sessions, and UEG Week would not be the top international digestive diseases meeting that it has become today.

Thank you!

We received a number of 3,170 abstracts in total for UEG Week 2018. In total, 2,214 abstracts were accepted, giving an acceptance rate of 69.84%. 337 abstracts will be delivered as oral presentations and 1,877 as posters. I am even more pleased to tell you that standards have again reached a very high level and we can expect to be exposed to most interesting research and great presentations.

This high volume and high standard confirm that UEG Week is the most important forum at which to present your best research. We have received 88 video cases and 254 clinical cases which were formally evaluated by the Scientific Committee for presentation in Vienna. As in previous years, late breaking abstracts have been scored by the Scientific Committee for presentation in Vienna.

The quality of reviewing this year was excellent, but if you have any further (positive or negative) comments, please do let us know!

Finally, but most importantly, thanks to all investigators both within and outside Europe who have submitted their research to the meeting, and who are clearly contributing to making UEG Week Vienna 2018 such a great success!

Herbert Tilg
Chair of the UEG Scientific Committee, Vienna 2018
Thanks to Partners, Sponsors and Exhibitors

Disclosure: There is an important heterogeneity among Crohn’s disease patients including clinical presentation and severity, disease location, disease behavior, presence of extra-intestinal manifestations or not, duration of symptoms and response to therapies. There is also a huge number of genetic combinations and expositions to environmental factors. At the molecular level, transcriptome performed on mucosal samples exhibit a striking heterogeneity. A molecular classification could prove more relevant to predict disease course, response to treatment and to identify new drug targets.

Aims and Methods: Our aims are to identify shared and unique molecular features, clinically significant subtypes, and potential therapeutic targets. We conducted an integrated analysis of several cohorts from the IBD Over Time (IBD OT) consortium, including surgical samples of ileal disease and endoscopic samples of both ileal and colonic disease. We also searched for data available in the public domain. We performed molecular clustering (ConsensusClusteringPlus) using mRNA from microarray and RNA-seq, after correcting for batch effect. Cibersort was used to impute immune cells fractions from bulk transcriptome. Finally, KEGG pathway analysis was performed to characterize identified clusters.

Results: We included in the analysis 580 samples of the IBDOT consortium (all by microarray) and 971 samples available in the public domain (508 by RNA-Seq and 736 by microarray). We saw a clear batch effect between the different platforms and cohorts. Colonic and ileal samples were well clustered together in each cohort. After correction for batch effect using biopsy location as a covariate, we identified 4 robust clusters of Crohn’s disease samples. Colonic clusters were dominated by inflammatory disease, ileal samples clustered mainly in 2 groups, APOA1-low highly inflammatory (C1), the other APOA1-high less inflammatory (C2). The fourth group (C4) was smaller and contained ileal samples only. Immune cells fractions showed a neutrophilic infiltration in C1, and a higher proportion of CD8 T cells and Gamma-Delta T cells in C2. Pathway analysis confirmed a typical IBD-like inflammation in C1, and a more subdued inflammation in C2.

Conclusion: We performed the first molecular classification of Crohn’s disease using more than 1500 gut samples from 6 different cohorts. 4 robust disease groups were identified, representing both disease location and levels of inflammation. Some limitations were the high heterogeneity of disease stage and limited data on disease characteristics for the data collected in the public domain. Future work could look at the disease course of these 4 clusters and determine their persistence over time.

Disclosure: Nothing to disclose.
Aims and Methods: NLPR6 is highly expressed by epithelial and goblet cells, but its function in hematopoietic cells is rather unknown. Here, we determined the expression of NLPR6 in vitro differentiated T cells, and in T cells after coculture of wt and NLPR6-deficient T cells to elucidate the influence of different microorganisms on NLPR6 expression by T cells. Results: NLPR6 is not expressed by naïve CD4 and CD8 T cells, B cells and bone marrow-derived macrophages in contrast to epithelial cells. When naïve T cells were differentiated to Th1 cells, Th1 cells express NLPR6, whereas only a minority of differentiated Th2 cells and Th17 have NLPR6. Promoter analysis of the human and mouse NLPR6 starting revealed binding regions for STAT1, STAT5a and Tasb2 (T-bet). T-bet induced NLPR6 expression in differentiated Th1 cells because NLPR6 was not detected in Tbx21-deficient T cells. The production of IFNγ by NLPR6-deficient Th1 cells is reduced compared to wt T cells, which is independent of inflammasome assembly, because in ASC-deficient T cell differences in IFNγ production was not observed. Moreover, differences in IL-13 and IL-17 production by in vitro differentiated Th2 and Th17 cells and differences in Foxp3 Treg cells between wt and NLPR6-deficient T cells were not observed. Transfer of wt CD45RBhigh T cells into RAG hosts resulted in somewhat increased body weight loss and increased disease scores compared to RAG hosts receiving NLPR6-deficient T cells two weeks after transfer. Conclusion: the expression of NLPR6 by differentiated Th1 cells is rather intrinsic and independent of different microorganisms because NLPR6 expression was observed by in vitro differentiated T cells. As consequence increased apoptosis was observed after transfer of NLPR6-deficient T cells in RAG hosts. NLPR6 facilitates the survival of CD4 T cells.

Disclosure: Nothing to disclose.

Endoscopic resection of polyps – Room B

OP005 ASSISTANCE OF A REAL-TIME AUTOMATIC COLON POLYP DETECTION SYSTEM INCREASES POLYP AND ADENOMA DETECTION DURING COLONOSCOPY: A PROSPECTIVE RANDOMIZED CONTROLLED STUDY

Introduction: Screening colorectal cancer can reduce the incidence and mortality of colorectal cancer through detection of polyps. However, a miss rate of up to 27% has been reported for adenomas.

Aims and Methods: The aim of this study was to investigate whether an automatic polyp detection system during colonoscopy increased the polyp and adenoma detection rate. Consecutive patients were prospectively randomized to undergo routine colonoscopy with or without assistance of real-time automatic polyp detection system providing a simultaneous visual notice and sound alarm when a polyp was detected. The automatic polyp detection system used in this study was a previously validated deep-learning polyp detection software.

Results: Out of 1,058 patients, 536 were randomized to a colonoscopy (control group) and 522 to a colonoscopy with computer-aided diagnosis (CAD group). There is no statistical difference between 2 groups in demographics and adenoma risk factors, including age (p = 0.16), gender (p = 0.19), BMI (p = 0.99), family/ personal adenoma history (p = 0.34/0.8), and family colon cancer history (p = 0.34). A total of 767 polyps, 422 adenomas and 31 serrated adenomas were detected. The polyp detection rate (PDR) of the control and CAD groups were 29.10% and 45.02% respectively (OR = 1.995, 95% CI 1.532-2.544, p < 0.001). The adenoma detection rates (ADR) were 20.34% and 29.12% respectively (OR = 1.61, 95% CI 1.23-2.135, p < 0.001). The average number of polyps detected were 0.50 and 0.95 respectively (Change Folds 1.89, 95% CI 1.63-2.192, p < 0.001).
OP006 POTENTIAL ACCEPTABILITY OF A WATCH-AND-WAIT APPROACH FOR DIMINUTIVE COLORECTAL ADENOMAS: FIVE-YEAR INDEPENDENT RISK FACTORS OF ADVANCED NEOPLASIA IN INDIVIDUALS WITHOUT UNEARTHED DIMINUTIVE ADENOMAS

Introduction: Removal of all colorectal adenomas during colonoscopy (CS) is recommended; however, the increasingly frequent detection of diminutive adenomas raises the question as to whether the removal of all is mandatory, balancing benefit and harms. The increasing use of antithrombotic drugs and smoking raises the question as to whether the removal of all is mandatory, balancing benefit and harms. Although the watch-and-wait approach is allowed in Japan, evidence is lacking for its acceptability for diminutive adenomas.

Aims and Methods: This study aimed to evaluate the cumulative incidence of advanced colorectal neoplasia (ACN) in individuals with untreated diminutive adenomas. To compare this with the incidence in those without adenomas.

The incidence was also evaluated after identifying and adjusting for risk factors for the incidence of ACN. Data from 1,378 consecutive asymptomatic individuals who underwent first screening CS and at least one follow-up CS without polypectomy at the Cancer Screening Center, National Cancer Center, Tokyo, between February 2004 and March 2013 were analyzed. Those with no adenomas or only non-advanced diminutive adenomas (<5 mm) confirmed by image-enhanced magnifying endoscopy were scheduled to undergo follow-up CS within 5 years after the initial CS without treatment. Thus, participants were classified into two groups: those with untreated diminutive adenomas (group A) and those without any adenomas (group B). The cumulative incidence of ACN in both groups was assessed in March 2018, using Gray’s test with consideration of competing risk situations. Multivariate analysis using the Fine and Gray model was performed to identify independent risk factors for the incidence of ACN in each group A and B. The cumulative incidence in ACN in both groups was assessed in March 2018, using Gray’s test.

Results: There were 361 and 1,017 participants in groups A and B, respectively. Only 18 and 14 were 76-untreated diminutive adenomas in each group A participant, and 355 participants (92.8%) had less than 3. During a median follow-up of 60.9 months (interquartile range 40.6-64.2), 21 ACNs, including one T1 colon cancer, were detected in 18 individuals. The number of endoscopies performed per individual was two in both groups (p = 0.93), and the 5-year cumulative incidences of ACN in group A and B were 1.4% (95% CI 0.5-3.4) and 0.8% (95% CI 0.3-1.7), respectively, with no significant difference between the groups (p = 0.23).

Endoscopic findings showed that no ACN grew from an untreated adenoma. The only independent risk factor for the incidence of ACN was current smoking (hazard ratio 5.7; p < 0.01); presence and number of untreated diminutive adenomas did not affect the incidence of ACN. After adjustment for smoking status, the 5-year cumulative incidences of ACN in groups A and B were 1.0% (95% CI 0.0-2.2) and 0.7% (95% CI 0.1-1.2), respectively.

Conclusion: The 5-year cumulative incidence of ACN in those with untreated diminutive adenomas was sufficiently low, and was similar to that in those without no adenomas, indicating the potential acceptability of a watch-and-wait approach for diminutive adenomas. The present findings may be useful for consideration of more practical screening and surveillance programs, although further assessment is required particularly for cases with many diminutive adenomas.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is strongly related with lifestyle. Advanced glycation end products (AGEs), derived also from diet, have been positively related with NAFLD, while its soluble receptor (sRAGE) acts as a decoy. The association of sRAGE with NAFLD has been scarcely studied. Moreover, little is known about lifestyle-related determinants of sRAGE levels.

Aims and Methods: The aim of this study was to test the association of sRAGE with lifestyle and NAFLD. A cross-sectional study among subjects 40-70 years old, participating in a screening study, undergoing abdominal ultrasonography to diagnose NAFLD and fasting blood tests. Nutritional index consumption was measured by food frequency questionnaire (FFQ) and lifestyle habits were measured by a structured questionnaire. Low sRAGE levels were defined as a level below the population lower tertile (5013 pg/ml).

Results: A total of 789 subjects had valid FFQ. High processed and/or red meat consumption (above the third tertile) was associated with higher odds of low sRAGE, adjusting for gender, age, abdominal obesity and caloric intake. Conversely, greater exercise time (above the median) was associated with reduced odds for low sRAGE (OR = 0.68, 0.49-0.94, p = 0.020). Subjects with low sRAGE had higher odds for NAFLD (OR = 1.51, 1.01-2.27, p = 0.045) and elevated ALT among NAFLD subjects (OR = 1.72, 1.12-2.64, p = 0.014) and among the entire sample (OR = 2.27 95%CI 1.28-4.04, p = 0.005).

Conclusion: Diet and exercise are associated with serum sRAGE levels and, in turn, low levels of sRAGE are associated with NAFLD and elevated ALT levels.

Introduction: Hypoxia and hypoxia inducible factors (HIFs) are believed to significantly affect the progression of chronic liver diseases (CLD). Recently, we showed that hepatectomy HIF-2alpha activation is a key feature in both human and experimental NAFLD and significantly contributes to disease progression.
A4

United European Gastroenterology Journal 6(8S)

Aims and Methods: In the present study we investigated the contribution of
hepatocyte HIF-2alpha in promoting the development of NAFLD/NASH-associated hepatocellular carcinoma (HCC). The role of HIF-2alpha was investigated
in human HCC liver specimens from NAFLD/NASH patients and in mice carrying hepatocyte-specific deletion of HIF-2alpha (HIF-2alpha fl/fl/Alb-Cre mice)
receiving diethyl-nitrosamine (DEN) administration plus choline-deficient Lamino acid refined (CDAA) diet (DEN/CDAA protocol).
Results: HIF-2 alpha, as detected by mRNA transcript and immunostaining, was
expressed in HCC specimens from NAFLD/NASH patients, with higher expression in patients experiencing early tumour recurrence. Following the treatment
with the DEN/CDAA protocol, mice carrying hepatocyte specific deletion of
HIF-2 alpha showed a significant decrease in either the volume and/or the
number of neoplastic liver tumour masses in transgenic mice as compared to
control littermates. Liver tumours in HIF-2 alpha transgenic mice were also
characterized by: i) a decrease of tumour associated macrophages and fibroblasts/myofibroblasts, as evaluated by F4/80 and alpha-smooth muscle actin
immunohistochemistry, respectively; ii) a significant decrease in transcript
levels for critical and HIF2alpha-related target genes, including c-Myc and
CXCR4.
Conclusion: These results indicate that the activation of HIF-2alpha in hepatocytes has a critical role in the development of experimental liver carcinogenesis in
a dietary NAFLD/NASH-related environment.

Introduction: The introduction of biological therapy has influenced healthcare
expenditures in inflammatory bowel disease (IBD) significantly. However, no
prospective long-term analysis of healthcare costs in patients with IBD in the
era of biologic treatments exists in Europe.
Aims and Methods: The aim of this study was to perform a cost analysis of a
pan-European inception cohort with five years of follow-up. The Epi-IBD cohort
is a population-based inception cohort of IBD patients diagnosed from 31 centers
in 20 countries in Western and Eastern Europe in 2010. Clinical and direct
cost data (investigations, treatments, hospitalization and surgery) were collected
prospectively. Patient management was left to the discretion of the treating gastroenterologists. Data are expressed as mean costs (E/patient-year). PY0 represents the inception year, and PY1, PY2, PY3 and PY4 are the four follow-up
years.
Results: The cohort included 1,362 IBD patients (Western Europe: 1,104; Eastern
Europe: 258), of which 52% had ulcerative colitis (UC), 37% Crohn’s disease
(CD) and 11% IBD unclassified. The age structure was: 40 y 45%, 41-60 y
31%, and  61 y 24%.
The total expenditures per year in CD and UC patients as well as the proportion
of expenditure spent on different categories of direct costs is shown in Table 1.
Total expenditure was higher in CD than UC, as was the annual percentage
outlay on biological therapy. In Western Europe, total annual costs were highest
in PY0 at E4,964, and then decreased as follows: PY1 E1,687, PY2 E1,585, PY3
E1,492, and PY4 E1,113. Expenditure on biologic therapy increased in this time
period (PY0 E338, PY1 E410, PY2 E440, PY3 E504, and PY4 E516). In Eastern
Europe, while overall healthcare costs were lower, similar observations were
made. Total annual costs were highest in PY0 at E2,227, and then decreased:
PY1 E934, PY2 E758, PY3 E643, and PY4 E734. Cost of biologic therapy was
the following: PY0 E31, PY1 E233, PY2 E355, PY3 E308, and PY4 E292. In
both regions this was paralleled by a steady decrease of costs of non-biologic
treatment, hospitalization and surgery.
In all centers the expenditure on investigations was highest in the year PY0. No
gender differences in costs were observed, however, patients aged  40 years
engendered higher costs than older individuals. The overall outlay on biological
therapy, expressed as a percentage of total expenditure, varied by age group:  40
yrs. 29%, 41-60 yrs. 21%, and  61 yrs. 11%.

[Table 1. Mean total expenditure (E/patient) and as well as the proportion of
expenditure spent on different categories of direct costs]
Conclusion: In this large population-based inception cohort of unselected IBD
patients, the overall direct expenditure on healthcare decreased over a 5-year
follow-up period. This period was characterized by remarkably increasing expenditure on biologics, particularly in CD patients, and decreasing expenditure on
standard medical treatments, surgery and hospitalization. Despite their known
high acquisition charges, these data indicate a cost-saving effect of biologic
medications.

The aim was to investigate the efficacy and safety of the sequential use of a second and a third anti-TNF agent after developing intolerance to an anti-TNF drug. Patients diagnosed with IBD from ENEIDA registry (a prospectively maintained registry from GETECCU) who switched to a second or a third anti-TNF after failure or intolerance to a previous anti-TNF drug were included. Efficacy, loss of response, and safety of the second and third anti-TNF were evaluated by logistic regression, Kaplan-Meier and Cox regression analyses.

Results: 1,022 patients that switched to a second anti-TNF were included (50% more severe age at diagnosis 31 years, 73% CD). The proportion of patients who became intolerant to the first anti-TNF were: primary failure (21%), secondary failure (51%), and intolerance (28%). A second attempt with an anti-TNF agent induced remission in 45% of patients in the short-term. 33% received concomitant immunosuppressive therapy. In the multivariate analysis, factors associated with a lower probability of achieving remission after a second anti-TNF were: type of IBD and combo therapy. Almost all patients who responded to a second anti-TNF subsequently lost response. Factors associated with loss of response of a second anti-TNF were: combo therapy (HR = 2.4; 1.8-3.2, p = 0.0001), to withdraw the first anti-TNF due to a primary failure (vs. intolerance) (OR = 1.6; 1.1-2.3, p = 0.007) and to withdraw the first anti-TNF due to secondary failure (vs. intolerance) (OR 1.5; 1.2-2.5, p = 0.003). The cumulative incidence of loss of response after achieving remission with the second anti-TNF (median follow-up of 19 months) was 45% (41-49%); 23% at 1 year, 38% at 2, 66% at 3, and 62% at 5 years. The incidence of loss of response to the second anti-TNF was 19% per patient-year of follow-up. The dose of the second anti-TNF was increased in 22% of patients during follow-up (median follow-up of 13 months); of these, 56% regained remission. At 1 year, 91% of these patients were in remission. The factors associated with a higher risk of loss of response were: UC vs. CD (HR = 1.6; 1.1-2.1, p = 0.005) and combo therapy (HR = 2.4; 1.8-3.2, p = 0.0001). The rate of adverse events after a second anti-TNF was 15%, and led to drug discontinuation in 61%. 71 patients switched to a third anti-TNF (55% IBD, mean age at diagnosis 32 years, 63% CD). The reasons for withdrawing the second anti-TNF were: primary failure (45%), secondary failure (39%), and intolerance (16%). Remission was achieved with the third anti-TNF in 55% of patients in the short-term. The incidence of loss of response was 22% per patient-year of follow-up (HR = 1.6; 1.0-2.6, p = 0.05). The cumulative incidence of loss of response was 38%: 18% at 1 year and 37% at 2 years. 7 patients (11%) had adverse events, but only one discontinued the therapy.

Conclusion: The efficacy of a second anti-TNF in IBD patients was associated with the reason for switching. Almost half of the patients who achieved remission with a second anti-TNF subsequently lost response. Factors associated with loss of response of a second anti-TNF were: type of IBD and combo therapy. Almost two-thirds of patients who received a third anti-TNF achieved remission; however, one-third of them lost response subsequently. The sequential use of a second and third anti-TNF is apparently safe.
Introduction: Studies comparing the characteristics of childhood-onset and adulthood-onset inflammatory bowel disease (IBD) in the biologic era are scarce. Aims and Methods: To compare the disease characteristics, the use of immunomodulators and biologic agents, and the need for surgery between childhood and adulthood-onset IBD.

IBD patients diagnosed from 2007 from the ENEIDA registry – prospectively maintained database promoted by GETECCU were included. Patients diagnosed at ≤16 years comprised the childhood-onset cohort (CC), and those diagnosed >16 years were the adult cohort (AC). Cox-regression analysis was performed to identify potential predictive factors to receive immunosuppressants, biological agents or surgery.

Results: From 21,200 patients, 96% comprised the AC and 4% the CC. Median follow-up was 54 months in the CC and 38 months in the AC (p < 0.001). The proportion of male gender, CD and family history of IBD was higher in the CC. CD patients in the CC had more extensive involvement while the proportion of patients with strictureing or fistulizing phenotype was higher in the AC. UC patients in the CC had more extensive involvement. Cumulative incidence of exposure to immunomodulators was higher in the CC: 54% at one year, 63% at 2 years, 70% at 3 years, 73% at 4 years and 87% at 5 years in the CC; and 34% at 1 year, 43% at 2 years, 48% at 3 years, 52% at 4 years and 53% at 5 years in the AC (p < 0.001). The cumulative incidence of exposure to biologic agents was higher in the CC: 25% at 1 year, 39% at 2 years, 45% at 3 years, 50% at 4 years and 65% at 5 years in the CC; and 16% at 1 year, 24% at 2 years, 29% at 3 years, 33% at 4 years and 37% at 5 years in the AC (p < 0.001). The proportions of patients and the cumulative incidence of surgery were similar in the CC and AC (17% vs. 15%, p > 0.05). Childhood-onset IBD was associated with higher risk of immunomodulator and biologic agents exposure. Childhood-onset IBD was not associated with higher risk of surgery (table 1).

Conclusions: Childhood-onset IBD patients diagnosed during childhood have differential characteristics (higher prevalence of CD, more extensive disease and more frequent family history). In addition, the use of immunomodulators and biologic agents is higher in childhood-onset patients. Despite of the higher burden of the disease in children, the rate of surgery is similar to that in the adulthood-onset IBD population.

Variable | Hazard ratio (95% confidence interval)
--- | ---
**USE OF IMMUNOSUPPRESSANTS**
Childhood-onset vs. adulthood-onset IBD | 1.6 (1.5–1.8)
Female gender | 0.94 (0.91–0.98)
Crohn’s disease (vs. ulcerative colitis) | 3.2 (3.09–3.4)
Family history | 1.08 (1.01–1.1)
Extraintestinal manifestations | 1.2 (1.1–1.3)
Smoking habit | 1.1 (1.05–1.16)
**USE OF BIOLOGIC AGENTS**
Childhood-onset vs. adulthood-onset IBD | 1.5 (1.4–1.7)
Female gender | 0.92 (0.85–0.95)
Crohn’s disease (vs. ulcerative colitis) | 2.5 (2.3–2.7)
Extraintestinal manifestations | 1.7 (1.6–1.7)
Smoking habit | 1.1 (1.04–1.18)
**SURGERY DURING FOLLOW-UP**
Childhood-onset vs. adulthood-onset IBD | 0.9 (0.8–1.2)
Female gender | 0.79 (0.73–0.86)
Crohn’s disease | 6.6 (5.8–7.4)
Immunomodulators before surgery | 0.36 (0.33–0.39)
Smoking habit | 1.2 (1.1–1.3)

[Variables associated with the risk of exposure to immunosuppressants, biological agents and surgery during follow-up.]

Disclosure: M. Chaparro has served as a speaker, or has received research or education funding from MSD, Abbvie, Hospira, Pfizer, Takeda, Janssen, Ferring, Shire Pharmaceuticals, Dr. Falk Pharma, and Amgen. J.P. Gisbert has served as a speaker, a consultant and advisory member for or has received research funding from MSD, Abbvie, Hospira, Pfizer, Kern Pharma, Biogen, Takeda, Janssen, Roche, Celgene, Ferring, Faes Farma, Shire Pharmaceuticals, Dr. Falk Pharma, Tillotis Pharma, Chiesi, Casen Fleet, Gebro Pharma, Osuka Pharmaceutical, Vifor Pharma.
especially in the era of biologic therapy. To date, no study has assessed indirect costs in IBD and UC patients in a population-based setting.

Aims and Methods: Our aim was to assess the indirect cost of CD and UC patients in a population-based inception cohort with 10 years of follow-up. All incident patients, diagnosed with CD (213) or UC (300) year 2003-2004 in a well-defined Copenhagen County, were followed prospectively until 2014. Employment status, sick-leave and social benefits are automatically registered in national registries through the unique 10 digit personal identification number given at birth or immigration. With use of these national registries, indirect cost of unemployment, sickness- and/ or disability assessed. The loss of income for the Danish government during unemployment was calculated using the mean income for the Danish popu-
lization of 41,970 EUR (value of 2017). Data were compared with a population of healthy controls matched by age, sex and municipality at diagnosis with a ratio of 1:20 (n = 10,259). Using multiple linear regression models, associations between indirect cost and multiple variables (gender, age, smoking status at diagnosis, disease behaviour, -location, -extension and diagnostic delay) were assessed.

Results: During follow-up, 139 [65%] CD and 181 [60%] UC patients had at least one episode of paid sick-leave (HR [95% CI] = 1.62) (2.6-19.8) months for CD and 5.1 (1.6-15.9; p = 0.2) for UC. The median cost of sickness benefits during follow-up for CD was 10,230 (3,900, 32,100) and 8,800 (2,400, 28,500) EUR for UC. No significant difference was found between healthy controls and IBD patients regarding length of paid sick-leaves (5.7 months [1.2, 16.4], p = 0.08) or sickness benefits (9,700 [2,100, 30,200], p = 0.2). Regarding unemployment, a total of 279,193 (543%) (CD: 12,377 [58%]; UC: 156,116 [52%]) patients were unemployed at least once during follow-up. In CD, the median length of unemployment was 5.3 (2.3-12) and 6.6 (2.14-18) in UC (p = 0.55). The median cost for unemployment benefits was 13,301,700 (4,703,100, 55,800,600) EUR for CD, and 12,301,400 (3,102,400, 47,103,300) EUR for UC patients. These estimates did not differ significantly from the healthy controls (5.9 [1.8, 14.4]; p = 0.6 and 13,400,000 [24,000,000, 46,600,300] p = 0.23, respectively). The median loss of tax income for the Danish government because of unemployment was 6,900,020 (2,001,800, 7,001,021,800) EUR, with a range from healthy controls (17,005,300, 16,401,200, 30,06) to 0 p = 0.06). The total indirect cost accounted for 19,714.4 million EUR (CD: 9.16 million, UC: 10.67 million). No factors were associated with the indirect cost in CD. In UC, age 17-40 years (OR: 1.53 [1.01, 2.11] 6), being male (OR: 0.90 [0.8, 1.0]) and current smoker (OR: 1.31 [1.0, 1.62]) at diagnosis were significantly associated with the indirect cost of 100,000 EUR.

Conclusion: In this population-based inception cohort with ten years of follow-
up, indirect cost of IBD patients did not differ from the general population. Furthermore, no significant increased expenses were found between CD and UC patients. These data indicate that in a country with universal and free access to healthcare current treatment strategies keep patients with IBD on the job market. Except for higher direct costs due to health care utilization, IBD patients had a higher indirect cost. In CD, 70% of the indirect cost was due to sickness benefits and unemployment. In UC, 65% of the direct cost was due to health care utilization.

Introduction: Nodular Oligomerisation Domain 2 (NOD2) is a key gene of immune recognition to the host defence toward pathogens. Several NOD2 variations associated with Crohn Disease (CD). Unexpectedly, these loss-of-function mutations are frequent in populations of European ancestry suggesting a model of balancing selection and thus a benefit to mutation carriers. NOD2 deficiency has been associated with a severe form of Yersinia pseudotuberculosis we hypothesized that NOD2 mutations have been selected during past plague outbreaks due to Yersinia pestis.

Aims and Methods: We performed a PubMed search looking for the frequencies of CD associated NOD2 mutations in healthy controls. Using historical data on plague outbreaks, we evaluated the rate of exposure to plague of the ancestors of the corresponding populations. Demography of cities and migration rates from the 14th century to the 19th century were also taken into account to evaluate the impact of putative confounding factors.

Results: The rates of the CD-associated NOD2 mutations in the general population were correlated with the intensities of plague outbreaks in Europe and the Mediterranean Basin. Statistical significance was obtained with the most frequent mutation (R702W, p = 0.03) and with the pooled three mutations (p = 0.023). The association remained significant when putative demographic biases were considered suggesting a robust finding.

Conclusion: This result argues for a selection of CD-associated NOD2 mutations by the various plague episodes which have occurred in Europe and the Mediterranean Basin since the Middle ages.

Introduction: Crohn’s disease (CD) is a chronic and progressive disease that changes its behavior over time. Transmural inflammation in CD leads to stric-
turing and/or penetrating complications.

Aims and Methods: We aim to evaluate the frequency of the long-term progres-
sion of patients with CD by classifying them according to short term behavior and to determine the main factors associated with this evolution.

A retrospective study was conducted with a prospective follow-up. Patients included had a minimum follow-up of 12 months. Montreal classification was assessed at the moment of the diagnosis and at the end of the follow-up period.

Results: Included 290 patients, 53.8% female. The behavior at presentation was inflammatory (B1) in 64.5%, stricturing (B2) in 23.4%, penetrating (B3) 12.1% and perianal disease was present in 18.6%. Behavior at the end of the follow-up was: B1 in 51.4%, B2 in 30.3% and B3 in 18.3%, perianal disease was identified in 20%. Globally we observed a change in behavior in 46 patients (15.9%); from B1 to B2 in 30 patients, B2 to B3 in 16 patients and B1 to B3 in 10 patients.

Illeocolic location (60.9% vs 45.1%; p = 0.049), age at diagnosis < 16 (8.7% vs 2%; p = 0.017), the use of steroids at diagnosis (43.2% vs 27%; p = 0.031) and less exposure to biological therapy (15.9 months vs 41.3 months; p < 0.001) were the risk factors associated with changing phenotype.

Regarding surgery, 70 patients (24.1%) were submitted to intestinal resection. Smoking status (42.9% vs 24.8%; p = 0.004), B2 (47.1% vs 15.9%; p < 0.001), B3 (42.9% vs 2.3%; p < 0.001), hospitalizations in the first year of diagnosis (52.3% vs 12.4%; p < 0.001), use of steroids at diagnosis (61.4% vs 23.6%; p < 0.001) were more frequently observed in patients submitted to surgery. Patients submitted to surgery were less frequently treated with biological therapy (8.7% vs 23.4%; p < 0.025).

Conclusion: In our cohort we observed a behavior progression in about one-sixth of patients. The most frequent change in behavior was to strictureing pattern. Strictureting and penetrating behavior, higher number of hospitalizations in the first year of diagnosis, use of steroids at diagnosis, smoking status, age at diagnosis and ileocolic localization were factors associated with an unfavorable clinical evolution. Patients that were submitted to surgery were less treated with biological therapy.

**Introduction:** Surveillance programs on high-risk individuals (HRIs) can detect precancerous pancreatic lesions (PCL) not previously identified. We report the results of the first-round of screening of the Italian multicenter program supported by the Italian Association for the study of the Pancreas (AISP).

**Aims and Methods:** The multicenter surveillance program includes: a) individuals with hereditary pancreatitis (HP), the second highest risk group after individuals with at least 2 relatives affected by pancreatic cancer; b) patients with at least one first-degree relative affected by pancreatic cancer (FPC-HRI); c) patients with at least two second-degree relatives affected by pancreatic cancer (2, SDR) with at least 1 FDR; d) patients with Peutz-Jegher (PJ) syndrome; e) patients with 2 relatives affected by pancreatic cancer (2, FDR) with at least 1 SDR; and f) patients with 3 relatives affected by pancreatic cancer (3, SDR), 1 of whom is a first-degree relative. These groups were combined into one cohort advised by FPC-HRI, HP, or probands with at least 2 relatives affected by pancreatic cancer. To evaluate the population-based screening, we included the cohort of HRIs suffering from PJ syndrome. To evaluate the population-based screening, we included the cohort of HRIs suffering from PJ syndrome.

**Results:** The first-round screening results in Italy report a high rate of pancreatic abnormalities. The rate of malignancies detected was higher in the cohort of FPC-HRI suffering from PJ syndrome than in the cohort of HRIs suffering from PJ syndrome (7.5% vs. 3.5%). The rate of malignancies detected was higher in the cohort of FPC-HRI suffering from PJ syndrome than in the cohort of HRIs suffering from PJ syndrome (7.5% vs. 3.5%). The rate of malignancies detected was higher in the cohort of FPC-HRI suffering from PJ syndrome than in the cohort of HRIs suffering from PJ syndrome (7.5% vs. 3.5%).

**Conclusion:** The first-round screening results in Italy report a high rate of pancreatic abnormalities. The rate of malignancies detected was higher in the cohort of FPC-HRI suffering from PJ syndrome than in the cohort of HRIs suffering from PJ syndrome (7.5% vs. 3.5%). The rate of malignancies detected was higher in the cohort of FPC-HRI suffering from PJ syndrome than in the cohort of HRIs suffering from PJ syndrome (7.5% vs. 3.5%). The rate of malignancies detected was higher in the cohort of FPC-HRI suffering from PJ syndrome than in the cohort of HRIs suffering from PJ syndrome (7.5% vs. 3.5%).

**Introduction:** The recent development of oral direct-acting antivirals (DAAs) has dramatically improved the efficacy of anti-hepatitis C virus (HCV) treatment, however, resistance-associated variants (RAVs) are associated with treatment failure in HCV-infected patients receiving DAA therapy. Although low- abundance RAVs are detected by real-time PCR as early as weeks after the start of therapy, it has been difficult to determine the clonal origin of RAVs using conventional short-read sequencing methods. Thus, in the current study, we investigated the viral dynamics in patients undergoing DAA therapy and explored the clonal origin of multi-drug resistant viral clones using single molecular real-time (SMRT) sequencing, so-called third generation sequencing, which can generate extremely long contiguous sequence reads.

**Aims and Methods:** Among 283 patients with genotype 1b HCV receiving DAAs therapy in our study group, 32 who failed to achieve a sustained virological response (SVR) were included in this study. First, conventional ultra-deep sequencing of NS3 and NS5A regions of HCV genome was performed in all patients using IonProton (ThermoFisher Scientific). Then, paired sera samples were collected before and after DAA therapy and from a cohort of 12 non-SVR patients, we applied SMRT sequencing using PacBio RSII (Pacific Biosciences) to determine the long contiguous sequences spanning >3000 bp of the NS3 to NS5A regions of each viral clone.

**Results:** Sixteen-deep sequencing detected representative RALs in all non-SVR patients at baseline, including NS5A-Y93H or L31M and NS5D-D168V. Importantly, at treatment failure, multi-drug resistant HCV clones were detected in all cases as the major population. Then, long contiguous sequences of each viral clone in 12 sera from 6 non-SVR patients (a total of 3601 clones) were determined by PacBio RSII. We found the substantial sequence diversity of viral isolates present at baseline in all cases, showing the high degree of genetic heterogeneity in HCV clones. All the nucleotide substitutions analyzed in each clone before and after treatment were compared, and we found significant linkage between some synonymous substitutions and major resistance-associated substitutions. For example, several synonymous mutations linked to NS5A-Y93H in a subpopulation of pre-existing viral clones at baseline were shared by multi-drug resistant viral clones at treatment failure. Phylogenetic analyses revealed a close genetic distance between pre-existing drug-resistant clones and multi-drug resistant viral clones at treatment failure. In addition, linkage analysis demonstrated that multiple drug-resistant mutations newly developed based on pre-existing RALs after DAA treatment in all non-SVR cases.

**Conclusion:** Comprehensive analysis of SMRT sequencing and conventional ultra-deep sequencing revealed that multi-drug resistant viral clones at treatment failure originated from a subpopulation of pre-existing RALs in HCV-infected patients. Those RALs were selected for and became dominant with the acquisition of multiple resistance-associated substitutions under DAA treatment pressure. These findings give us a clue to a better understanding of treatment failure mechanisms with anti-HCV therapy.

**Disclosure:** Nothing to disclose
Aims and Methods: The objective of this analysis was to use eDISH to determine if patients with NASH treated with OCA showed increased markers of liver injury or whole liver dysfunction. eDISH methodology was applied to 278 patients treated with placebo (n = 140) or 25mg OCA (n = 138) from FLINT and 84 patients treated with placebo (n = 21), 5mg OCA (n = 20), 10mg OCA (n = 21), or 20mg OCA (n = 22) from CONTROL. Individual CONTROL and FLINT patients were matched on the basis of baseline values of alanine aminotransferase (ALT) and total bilirubin throughout the double-blind treatment phase were plotted on an x-y chart as logarithm_{10} values of multiples of elevations above the upper limit of the normal reference range (S ULN).

Results: Overall, no OCA-treated patients were in the Hy’s law quadrant (>3x ULN for ALT and >2x ULN for total bilirubin) compared with 1 placebo-treated patient in FLINT. The proportion of patients with peak ALT and total bilirubin values in the lower left quadrant (representing normal or near normal range) was higher in OCA-treated patients compared with placebo (FLINT: 91% OCA vs 84% placebo; CONTROL: 91% OCA vs 86% placebo). 8% of OCA-treated patients from both FLINT and CONTROL presented in the Temple’s corollary quadrant (>3x ULN for ALT and <2x ULN for total bilirubin) vs 14% (in both studies) for the placebo-treated patients. Across both studies (N = 362), 4 patients were in the cholestasis quadrant (>2x ULN total bilirubin and <3x ULN for ALT); 1 placebo-treated patient and 3 OCA-treated patients, including 1 patient with Gilbert’s syndrome.

Conclusion: In these 2 placebo-controlled, double-blind NASH studies, the eDISH analysis showed no trend for liver injury with OCA at doses up to and including 25 mg.

Disclosure: This study was funded by Intercept Pharmaceuticals Inc.

Aims and Methods: The first study in this series aimed to evaluate the feasibility and safety of EUS-guided photodynamic therapy (EUS-guided PDT) with a second-generation photosensitizer for unresectable pancreatic cancer. Patients with unresectable pancreatic cancer were prospectively enrolled in a single tertiary center between December 2015 and January 2018. Patients were photosensitized with chlorin e6 derivatives (Photolon®). After endoscopic ultrasonography (EUS-guided PDT) with a second-generation photosensitizer for unresectable pancreatic cancer. Patients with unresectable pancreatic cancer were prospectively enrolled in a single tertiary center between December 2015 and January 2018. Patients were photosensitized with chlorin e6 derivatives (Photolon®). After endoscopic ultrasonography (EUS-guided PDT) with a second-generation photosensitizer for unresectable pancreatic cancer. Patients with unresectable pancreatic cancer were prospectively enrolled in a single tertiary center between December 2015 and January 2018. Patients were photosensitized with chlorin e6 derivatives (Photolon®). After endoscopic ultrasonography (EUS-guided PDT) with a second-generation photosensitizer for unresectable pancreatic cancer. Patients with unresectable pancreatic cancer were prospectively enrolled in a single tertiary center between December 2015 and January 2018. Patients were photosensitized with chlorin e6 derivatives (Photolon®).
Aim and Methods: Therapies based on biomarker profiles.

Results: 40 patients were enrolled, 35 tumor samples were analyzed and interpretable results were obtained from 31 patients. At least 1 relevant biomarker was found in all cases. We found mutations in KRAS (n = 24), TP53 (n = 17), SMAD4 (n = 3), BRCA1 (n = 4; 3 germline, 1 somatic), CDKN2A (n = 9; ATM n = 3; LOF), APC (n = 4), and MSH3 (n = 15; 1 germline). MH Guide made treatment recommendations in 30:31 cases: PARP-inhibitors (n = 26), MEK/RAF inhibitors (n = 20), CDK inhibitors (n = 9), other kinase inhibitors (n = 3), mTOR inhibitors (n = 2). The molecular tumor board (MTB) agreed in 26 cases: 2 patients received other second-line line therapy and 2 BSC. 3 patients died before and 2 during analysis, 1 prior to the MTB, 2 before start of therapy and 3 shortly after. Today, the major cause of death is disease progression. Chemotherapy for which they had a toxic effect was given to 13/27 patients and 7 had toxicity of grade 3 or above.

Conclusion: Evidence-based personalized treatment recommendation in PDAC is feasible and molecular stratification of PDAC patients routinely leads to recommendation of off-label use of registered drugs. Today, we have found tumors with HCC, 30-59 15.0 12.3–18.0 18.4 12.1–26.7 30-59 39.1 31.5–47.9 39.0 23.1–61.6 41.1–73 71.8–133 19.6–183 1.44–317 1.44–317 Ø.003, n = 5,578) and patients with missing information on cirrhosis status (7.6% vs. 0%, p = 0.048, n = 365), respectively.

Conclusion: Statin use was associated with reduced risk for HCC development in chronic hepatitis B patients, regardless of cirrhosis status. Statin treatment may decrease HCC risk, which warrants prospective validation.

Introduction: The most common causes of acute nonvariceal upper gastrointestinal bleeding (AUGIB) are peptic ulcer bleeding and haemorrhagic gastritis. The use of non-steroidal anti-inflammatory drugs (NSAIDs) and low-dose acetylsalicylic acid (LDA) are known risk factors for both COX-2 selective NSAIIDs are considered safer in terms of bleeding.

Aims and Methods: To identify patients with AUGIB who use LDA and NSAIDs, determine the severity of bleeding, outcomes and potential risk factors for adverse outcomes. Retrospective, prospective analysis of all patients over 18 years of age consecutively admitted for AUGIB in a tertiary centre in Latvia – Riga East Clinical University Hospital from November 2013 to December 2014. Data was collected regarding history of drug use, bleeding-related interventions, length of hospital stay and outcomes. Forrest classification was used to evaluate the severity of bleeding, data was entered into the database with consecutive statistical analysis using SPSS 20.0.

Results: 236 patients with AUGIB were enrolled (138 (58%) men, 98 (42%) women, mean age 62 ± 17.36 years). Peptic ulcer disease (PUD) was the most common diagnosis (n = 180, 73%). Out of all patients, 90 (38.1%) were NSAIDs users (more often women (46/44)), 27 (11.4%) used oral anticoagulants (mean past use of 10.8 years) and 52 (22.4%) used alcohol (mean age 47 ± 11.61 years). NSAIDs use was associated with more frequent PUD bleeding (r = 0.347, p < 0.001). Out of 26 patients with Forrest I type (IA and IB) peptic ulcer bleeding, 12 (46%) used NSAIDs, 9 (34.6%) were on LDA therapy, 3 (11.5%) were alcohol users. The most commonly used NSAIDs were diclofenac (n = 24, 26%) and ibuprofen (n = 8, 9%). There was only one patient on COX-2 selective NSAID therapy, who was admitted with Forrest II B bleeding. 108 patients (45.7%) were hospitalised in intensive care unit, most often with Forrest IIIB PUD bleeding – 36 (33.3%). Tranfusion of red blood cells was required in 133 (56.3%) cases, fresh frozen plasma in 106 (44%) cases and cryoprecipitate in 39 (16.5%) cases. Surgery was performed in 37 (15.6%) patients. Most of the patients requiring surgical intervention were on NSAID therapy (22/37, p = 0.004, Pearson Chi-Square). Bleeding-related in-hospital death occurred in 24 (10%) cases, mostly in patients with recurrent PUD bleeding. There was a statistically significant age difference between patients who recovered and those who died (n = 212, 61 ± 17.14 vs. n = 24, 78 ± 10.04, p < 0.001). The difference in length of hospital stay between NSAIDs users and non-users was marginally significant (p = 0.058, Mann-Whitney Test).

Conclusion: 1. LDA and NSAIDs remain the most common risk factors for AUGIB and are associated with the need for surgical intervention. 2. Bleeding-related mortality and need for surgery during hospitalisation remain high. 3. Important prophylactic measures should include patient education about risks, adequate gastroprotection and minimisation of alcohol use.

Background: Emerging evidence suggests that the benefit of dual antiplatelet therapy (DAPT) might be independent of the platelet inhibitor used. However, this approach has not been prospectively validated in registry data. DAPT has been associated with a higher risk of bleeding complications compared to single antiplatelet treatment. Methods: We performed a retrospective evaluation of patients who received a percutaneous coronary intervention (PCI) to estimate the risk of both any major bleeding (MB) and major bleeding complications (MBC) requiring urgent surgery or blood transfusion (BTT) in those receiving clopidogrel (CP), ticagrelor (TCA) or prasugrel (PSG). Results: A total of 44,091 patients were included in the study. MB was observed in 3,254 patients (7.4%) and MBC/BTT occurred in 883 patients (2%). There were no significant differences in the risk of MB (p = 0.61) or MBC/BTT (p = 0.52) between the three treatment groups. Conclusion: The use of CP, TCA, or PSG did not lead to differences in the rate of MB or MBC/BTT after PCI. The risk of major bleeding complications requiring urgent surgery or blood transfusion was similar in all three groups.
Introduction: Dual antiplatelet therapy (DAPT) decreases major adverse cardio-vascular events after a percutaneous coronary intervention (PCI). New and potentially more effective antiplatelet agents such as ticagrelor or prasugrel combined with aspirin (ASA) are being prescribed preferentially to younger and healthier patients based on the potential higher risk of GI bleeding. However, very few data are available concerning the occurrence of GI bleeding associated with these new compounds when compared to classical DAPT with clopidogrel in common clinical practice.

Aims and Methods: We aimed to determine the risk and type of major and minor GI events in patients with DAPT and type of DAPT, and to analyze PPI therapy regimens during and after DAPT withdrawal. This was a retrospective observational cohort study of patients who started DAPT after a PCI from January 2013 to December 2017. All patients underwent upper endoscopy, and were on DAPT with either clopidogrel, ticagrelor or prasugrel, respectively. There were statistically significant differences in baseline characteristics between the groups, indicating that younger and healthier people received therapy with the new antiplatelet agents (table 1). Most patients (661/710; 93.1%) received PPI therapy while DAPT was active and after withdrawal (582/661); 88%; 32 patients (4.5% (32/710)) developed a major GI bleeding and 18.9% (134/710) developed anemia. Lower GI bleeding was more frequent than upper GI bleeding (78.1% (25/32) vs 18.8% (6/32) and 3.1% (1/32) had obscure GI bleeding. There were no differences in the occurrence of major GI bleeding (5.1% vs 3.9%, 0.475), non-gastrointestinal bleeding (10.4% vs 10.5%, 0.001), ischemic events (13.6% vs 9.6%, 0.103) or death (4.8 vs 2.1%, 0.066) between patients on DAPT with clopidogrel or new antiplatelets; however, anemia was most common in the group of DAPT with clopidogrel (21.8% vs 15.6%, 0.035). After adjusting for major confounding factors, including age, comorbidities, anticoagu- lant therapy and GI risk, there was no differences in the risk of GI events between groups (clopidogrel vs new agents overall GI events HR: 0.839 (0.579–1.215), major GI events HR: 1.050 (0.448–2.461), minor GI events HR: 0.801 (0.531–1.207).

Conclusion: DAPT is more frequently associated with lower than upper GI bleeding. Prasugrel- or ticagrelor-based DAPT was not associated with increased risk of either GI (upper or lower) bleeding when compared to clopidogrel-based therapy. The potential benefits of the new antiplatelets might be extended to all patients undergoing PCI based on GI risk factors.

Results: 519 patients with a diagnosis of upper gastrointestinal bleeding were included in the study. 279 patients differed from the remaining 240 patients in comorbidity (82.1% vs 37.1%, p < 0.001) and in antipeptide (31.2% vs. 5.4%, p < 0.001), anticoaguclants (26.9% vs.5%, p < 0.001) and NSAIDs (16.1% vs. 30.8%, p < 0.001) use. No differences were found in the need for endoscopic, interventional radiology and surgery procedures; blood units transfusions, days of hos- pital stay, in-hospital rebleeding and in-hospital mortality. Independent predictors for in-hospital mortality in EPs were onset as hematemesis (HR 2.73; 95% CI 1.105–6.84; p = 0.030), rebleeding (HR 6.251; 95% CI 2.731–15.79; p < 0.001) and antiplatelets (HR 0.290%; CI 0.290–9.96; p = 0.046). However, elderly patients presented a higher rate of delayed 6-months mortality (15% vs. 7.7%, p = 0.016) and were related with GI bleeding. Independent predictors for this event in EPs were albumin (HR 0.426; 95% CI 0.236–0.712), and creatinine levels (HR 1.927; 95% CI 1.178–3.150; p = 0.009).

OP028 SHOULD WE BE USING THE SHOCK INDEX TO ASSESS PATIENTS PRESENTING WITH UPPER GI BLEEDING?

Introduction: Upper GI bleeding (UGIB) is a common cause of hospitalisation. The admission Rockall (ARS), Glasgow-Blatchford (GBS) and AIMS65 scores are validated pre-endoscopy risk assessment tools. The UK NICEPOD report into UGIB used Shock Index (SI = pulse/systolic blood pressure) to assess risk of poor outcome. However existing data on SI are mostly from trauma settings. The limited data in UGIB suggest SI > 0.7, or SI > 1 may predict need for endoscopic therapy or mortality. Our aim was to assess the accuracy of SI to predict clinical outcomes after UGIB.

Aims and Methods: We collected demographic, clinical and laboratory data on consecutive patients admitted to 6 large hospitals across the UK, USA, Denmark, Singapore, and New Zealand over 12 months. We compared the SI, AIMS scores, GBS and AIMS65 and the new international bleeding risk score (IBRS) in their ability to predict need for endoscopic therapy, need for major transfusion (≥4 units PRBCs) and death. We also assessed score thresholds for identifying patients at low risk of death, and whether adding the SI as a parameter to the IBRS improved its predictive accuracy.

Results: 3012 patients (mean age 65yrs; 58% men) were studied. 574 (19%) required endoscopic therapy and 396 (13.3%) needed major transfusion. 30-day mortality was 7%. This table compares AUC/ROCs of the scoring systems for predicting outcomes.

References
**Aim and Methods:** Patients with manometric findings consistent with AC and no obstructive cause without prior therapy were randomly assigned to either LH or POEM from a single tertiary center. Demographic data, procedure info, Eckardt score, LES pressure, follow-up reflux esophagitis, adverse events and length of stay were collected. Student’s t-test, Chi square and Logistic regression analyses were conducted.

**Results:** 40 patients were enrolled (26 M, mean age 48.5) from Mar 16 to Jan 17. 29 patients performed POEM in 20 patients and LH in other 20. Both groups presented significant reduction in Eckardt scores compared to baseline (1.07 vs. 5.06 in POEM and 1.03 vs. 5 in LH, p < 0.001) and in LES pressure (7.89 vs. 7.01 in POEM and 7.03 vs. 6.73 in LH, p < 0.0001). Operative time was significantly lower for POEM (p < 0.001). There were no differences between POEM and LH in length of hospital stay (p = 0.173).

**Conclusion:** POEM as effective and safe as LH for the treatment achalasia but carries shorter duration of procedure. POEM patients present higher esophagitis rate.

**Disclosure:** Nothing to disclose.

\[ p < 0.001 and \ p > 0.001 when compared to SI \]

For predicting need for endoscopic therapy or major transfusion, SI had lower accuracy than GBS and IBRS, but similar to AIMS65 and ARS. In contrast to SI≥1, GBS≥7 correctly identified the majority of patients needing endoscopic therapy (80% vs 21%; p < 0.001). For predicting 30-day mortality, SI had lower AUROC than all other scores. GBS was superior to SI< 1.7 at predicting low-risk of death (mortality rate 0.35% vs 5.2%; p< 0.001). Patients with SI>1 had lower mortality than those with IBRS≥8 (15.3% vs. 31.4%; p< 0.001) and IBRS correctly identified a greater proportion of those who died as being high risk (49% vs 28%; p< 0.001). Adding SI to the IBRS did not improve its predictive accuracy (AUROC 0.864 vs 0.863).

**Conclusion:** Existing pre-endoscopy risk scores are superior to the SI in predicting need for endoscopic therapy, major transfusion or mortality after UGIH. Most patients who reach these important clinical endpoints are classified as low risk by SI.

**Disclosure:** Due to be presented at the British Society of Gastroenterology national meeting in June 2018.

significantly higher health care cost. To date, there is no data regarding comparison between EUS-guided coils+CYA vs. EUS-guided coils alone. Aims and Methods: We aim to compare efficacy and safety of coils+CYA vs. coils alone in the EUS-guided management of GOV II and IGV I. Single-center, randomized, controlled trial (March 2016 – June 2017). Study protocol was approved by Institutional Review Board. Written informed consent was obtained. Selection criteria: 18-80 yo, hepatic cirrhosis with endoscopic evidence of GOV II or IGV I (Sarin classification), >50000 platelets/mL, INR ≤2, not into Hepatocellular Syndrome. After randomization, two groups were formed. EUS procedure was performed by a 1st endoscopist, blind to patients' history. EUS follow-up was performed 3 months later. CYA: 120 mg intrasophageal injection, 10% less re-bleeding, preventing 14% GV reappearance and saving 14% re-interventions rate, lower re-bleeding, and GV reappearance prophylaxis; compared with Coils alone, CYA represent an effective technique

Results: Of all study participants 15% reported having IBS, 19% having BS-2w, and 47% being stressed. IBS and BS-2w were strongly correlated (r = 0.6), and these subjects were more often females, were younger, had lower physical activity level, were more often smokers and users of probiotics, were more likely to be stressed and suffered from worse psychological well-being, compared to the healthy subjects. The fecal samples of IBS were significantly enriched with Butyribibacterium (p = 0.030), Dorea (p = 0.039), Fusobacterium (p = 0.027), Streptococcus (p = 0.008) and Streptophyta (p = 0.015), and had significantly less Bacteroides (p = 0.018), Butyricimonas (p = 0.022), Christensenella (p = 0.010), Fecalibacterium (p = 0.048), Lachnobacterium (p = 0.043), Rikenellaceae (p = 0.009), and SH46 (p = 0.001). Individuals who reported having bowel symptoms last 2 weeks were significantly enriched with Blautia (p < 0.001), Dorea (p = 0.013), Ruminococcus (p = 0.008), and Streptophyta (p = 0.004), and had significantly less Christensenella (p = 0.003) and Lachnospiraceae on diarra (p for interaction = 0.002), where the association only occurred in stressed individuals.

Conclusion: This is to the best of our knowledge the first study to investigate relationship between gut microbiota and IBS in a general population. We observed that specific bacteria significantly differed between individuals with and without IBS and bowel symptoms. Diarrhea was the bowel symptom with most and strongest associations of different microbiota. Self-perceived stress was found to modify the composition of gut microbiota in relation to bowel symptoms.

Introduction: Abdominal pain in association with altered bowel habits, without any obvious organic changes, are called functional bowel disorders, with irritable bowel syndrome (IBS) being the most common entity. The etiology is unknown, but an altered gut microbiota has been observed in some studies, with incongruent results.

Aims and Methods: Our aim was to examine the gut microbiota composition in a large population-based cohort, the Malmö Offspring Study (N = 1888, mean age 40b, 53% with respect to presence or absence and severity of bowel symptoms and self-perceived stress. The participants completed questionnaires about socioeconomic factors, lifestyle and medical history, and were asked if they have (yes/no) 1) IBS, 2) experienced any bowel symptoms during the last 2 weeks (IBS-2w), 3) been commonly stressed during the last 12 months. Participants with BS-2w completed a Visual Analog Scale for Irritable Bowel Syndrome (VAS-IBS) including abdominal pain, diarrhea, constipation, bloating and flatulence, vomiting and nausea and psychological well-being. The 16S rRNA gene was sequenced (2300bp, V1-V3) from fecal samples. To identify OTUs at genus level the sequences were binned together by FLASH and QIIME and matched to the Greengenes (13.8) reference database. The OUT data was normalized using cumulative sum scaling, and rare- and low abundance OTUs were filtered out, resulting in 67 identified genus. Associations between the gut microbiota and IBS and BS-2w were analyzed by logistic regression, and items in VAS-IBS by general linear model, adjusting for age, sex, physical activity and smoking. We further studied if the associations were modified by self-perceived stress.

Results: Of all study participants 15% reported having IBS, 19% having BS-2w, and 47% being stressed. IBS and BS-2w were strongly correlated (r = 0.6), and these subjects were more often females, were younger, had lower physical activity level, were more often smokers and users of probiotics, were more likely to be stressed and suffered from worse psychological well-being, compared to the healthy subjects. The fecal samples of IBS were significantly enriched with Butyribibacterium (p = 0.030), Dorea (p = 0.039), Fusobacterium (p = 0.027), Streptococcus (p = 0.008) and Streptophyta (p = 0.015), and had significantly less Bacteroides (p = 0.018), Butyricimonas (p = 0.022), Christensenella (p = 0.010), Fecalibacterium (p = 0.048), Lachnobacterium (p = 0.043), Rikenellaceae (p = 0.009), and SH46 (p = 0.001). Individuals who reported having bowel symptoms last 2 weeks were significantly enriched with Blautia (p < 0.001), Dorea (p = 0.013), Ruminococcus (p = 0.008), and Streptophyta (p = 0.004), and had significantly less Christensenella (p = 0.003) and Lachnospiraceae on diarra (p for interaction = 0.002), where the association only occurred in stressed individuals.

Conclusion: This is to the best of our knowledge the first study to investigate relationship between gut microbiota and IBS in a general population. We observed that specific bacteria significantly differed between individuals with and without IBS and bowel symptoms. Diarrhea was the bowel symptom with most and strongest associations of different microbiota. Self-perceived stress was found to modify the composition of gut microbiota in relation to bowel symptoms.

Introduction: The intestinal microbiota has been implicated as an important factor in the pathogenesis of irritable bowel syndrome (IBS) however the mechanisms by which the intestinal microbiota affects the presence and/or severity of IBS symptoms are unclear. Recent advances suggest a role for bile acids in causing alterations in bowel functions including stimulating bowel secretion and increase in peristalsis and symptoms of diarrhea and watery stools that are commonly reported in patients with IBS. It is well known that the conversion of primary bile acids into (highly colonic irritant) secondary bile acids is entirely dependent on intestinal bacterial enzymes. However, the relation between the intestinal microbiota, bile salts composition and metabolism and IBS clinical symptoms.
Fresh fecal samples were collected from subjects who met the Rome III criteria for IBS, and non-IBS controls. IBS principal symptoms (abdominal pain, change in bowel movements and bloating) were assessed using validated measures on a daily diary. Overall IBS symptoms were assessed using the IBS symptom severity scale (IBS-SSS) and intestinal sensation by Visceral Sensitivity Index (VSI). The intestinal permeability was investigated by caecum supernatant and analyzed using an in-house validated, published pipeline (1), predicted metagenomics with PICRUSt(2) and concentrations of fecal bile acids by UPLC-MS system(3).

Mann-Whitney test was used for univariate analysis, and PERMANOVA(3) was used for between group comparisons. Pearson correlations were performed with log transformed bile acid concentration and clinical data.

Results: 3 Fecal samples from 25 IBS and 27 non-IBS subjects were analyzed. We identified 9 major phyla of which Firmicutes (58.22 ± 2.56%, mean ± SEM), Bacteroidetes (36.32 ± 2.84%), Actinobacteria (2.89 ± 0.66%) and Proteobacteria (1.37 ± 0.24%) were the most abundant in all subjects. There were no between groups-composition difference at the phylum and community levels. We identified 21 bile acids in stool, with no significant difference in concentration of individual bile acids between IBS and non-IBS samples. In patients with IBS, fecal conjugated primary bile acids (r = 0.62, p = 0.014) and conjugated secondary bile acids (r = 0.49, p = 0.074) and conjugated tertiary bile acids (r = 0.74, p = 0.022) showed a positive relationship with IBS-SSS. The 3rd conjugated bile acid also correlated with pain severity in IBS (positive correlation, r = 0.6809, p = 0.0435) and VSI score (negative correlation, r = 0.7905, p = 0.0195). No association was found between unconjugated bile acids and any of the clinical variables. Predictive metagenomic analysis of bile salt hydrolase (BSH) bacterial enzymatic activity showed negative correlation with glycine-conjugated primary bile acids (r = -0.473, p = 0.0305). More interestingly, an inverse trend was found between fecal BSH activity and IBS-SSS (r = -0.416, p = 0.0458).

Introduction: The intestinal barrier and epithelium play a key role in the pathogenesis of several gastrointestinal diseases, such as inflammatory bowel diseases and Irritable Bowel Syndrome (IBS). Among possible pharmacological interventions to restore epithelial barrier, an interesting perspective is represented by probiotics and prebiotics commonly used in clinical practice. Escherichia coli Nissle 1917 (EcN) is a probiotic effective in the maintenance of remission of ulcerative colitis, although the underlying molecular mechanisms remain unclear.

Aims and Methods: The aim of this study was to characterize the potential effect of EcN in reversing the increase of intestinal permeability caused by the media tors spontaneously released by IBS biopsies, by known inflammatory stimuli and to evaluate the molecular mechanisms involved. CaCo-2 cells were used as an in vitro model of intestinal epithelial barrier. Two concentrations of EcN (104 and 105) were applied to CaCo-2 with or without SLIGRL (a protease-activated receptor-2 activating peptide), tumor necrosis factor (TNF)-α, interferon (IFN)-γ and inflammatory mediators spontaneously released (SUP) by mucosal biopsies of patients with IBS and healthy controls (HC). Paracellular permeability was evaluated using sulfonic acid-conjugated to fluorescein (FITC). qPCR was used to assess mRNA expression of tight junction proteins, zonula occludens-1 (ZO-1), claudin-1 and occludin.

Results: EcN induced a dose-dependent reinforcement of CaCo-2 monolayer of 52% (104, p < 0.05) and 32% (105) compared to untreated CaCo-2 (CTR). SLIGRL 30uM and 200uM induced a significant increase in CaCo-2 permeability compared to CTR (p < 0.05); the co-incubation of SLIGRL and EcN induced a recovery of epithelial integrity compared to SLIGRL alone. TNF-α and IFN-γ strongly induced EcN sensitivity compared to EcN alone in Spontaneous PB of patients with IBS induced a significant increase of paracellular permeability compared to HC SUP (p < 0.05). The co-incubation of EcN with IBS-D or -C SUP induced a recovery of permeability rate compared to SUP alone (p < 0.05). No effect of EcN was observed with IBS-M SUP. qPCR analysis showed EcN induced a significant increase in Zo-1 and occludin expression compared to CTR. Permeability rate significantly correlated with severity and frequency of abdominal pain and distension.

Conclusion: EcN reinforces the intestinal epithelial barrier enhancing the expression of tight junction proteins. EcN reverses the increase of epithelial monolayer permeability induced by inflammatory stimuli and IBS SUP. These results pave the way to future studies to understand the potential application of EcN in IBS.

Disclosure: The aim of this study was to assess the effect of modulating the gut microbiota by faecal microbiota transfer (FMT) on visceral hypersensitivity in IBS patients. As part of a randomised, placebo-controlled, double-blinded clinical trial (registered at clinicalTrials.gov under NCT02092402), 16 IBS patients were randomly assigned to receive FMT either from a healthy donor (treatment group), or from their own faecal material (placebo group). The faecal material was administered into the caecum by whole colonoscopy after a bowel cleansing. In addition to completing questionnaires for assessing IBS symptoms (IBS-SSS, GSRS-IBS), the patients underwent a barostat procedure at baseline and 8 weeks after FMT. Before assessment, patients fasted overnight and were placed in a left lateral position. The barostat catheter (600 mL, Mui Scientific, Ontario, Canada) was placed 15 cm into the rectum. Rectal distensions were performed according to previous studies using an electronic distension barostat device (Distender series II, G&J Electronic Inc., Toronto, Canada) [2, 3]. In short, intermittent semi-random staircase distensions of 60 seconds duration were separated by intervals of 30 seconds of baseline pressure. During each distension, subjects reported their perception of pain, discomfort, and urge, respectively, using 100 mm visual analogue scales (VAS). VAS scores were fit to a logistic function for model and evaluated at fixed pressures of 40, 50, and 60 mmHg. The fitted baseline-corrected VAS values were then compared before and after FMT using Wilcoxon signed rank test, and between treatment and placebo using Mann-Whitney U-test.

Results: Evaluable barostat data was available from n = 14 participants. No statistically significant differences in the patients’ perception of pain and discomfort were found before and after FMT, neither in the treatment (n = 8) nor the placebo group (n = 6). The perception of urge was significantly lower in the placebo group compared to the treatment group at 20, 40, and 50 mmHg 8 weeks after FMT. Even though a relief in symptoms after FMT was found in the treatment group compared to baseline, this was not associated with decreased visceral hypersensitivity.

Conclusion: The beneficial effect of FMT from healthy donors on the symptom scores in IBS patients does not seem to be mediated by reduced hypersensitivity. The reduced perception of urge in the placebo group could be a result of the bowel cleansing prior to the colonoscopy. The absence of this effect on urge in the placebo group compared to the treatment group might be due to a reaction of the host mucosa to the introduction of a new, foreign microbiota. Further analyses need to be performed to study what contributes to the positive effect of FMT in IBS patients.

Disclosure: Nothing to disclose.

Introduction: Irritable bowel syndrome (IBS) is associated with an intestinal dysbiosis, and fecal microbiota transplantation (FMT) has been hypothesized to have a positive effect in patients with IBS. We performed a randomized, double-blind placebo-controlled trial to investigate if FMT resulted in an altered gut microbiota and improvement in clinical outcome in IBS patients.

Aims and Methods: We performed this study in 52 adult patients with IBS (based on Rome III criteria) with moderate to severe disease activity based on a symptom score of at least 175 in the IBS-severity scoring system (IBS-SSS). Our primary endpoint was the difference in improvement in IBS-Score at 2 months. At the screening visit, clinical history and symptoms were assessed and fecal samples were collected. Patients were then randomized to FMT or placebo capsules for 12 days and followed for 6 months. Study visits were performed at baseline, 1 month, 3 months and 6 months, where patients were asked to register their symptoms using the IBS-SSS and IBS specific quality of life (IBS-QoL). Prior to each visit fecal samples were collected, inclusive of a sample 3 days after treatment was completed (day 15).

Results: A significant difference in improvement in IBS-SSS score was observed 3 months after treatment (p = 0.012) favoring placebo. This was similar for IBS-QoL data after 3 months (p = 0.003) favoring placebo. Patients receiving FMT capsules had an increase in biodiversity to the extent that this group wasn’t statistically distinguishable from the donors, and the placebo patients remained statistically indistinguishable from their pre-treatment state (Mann-Whitney U-test, p < 0.05). All participants completed the treatment and no severe adverse events were registered throughout the study period.

Conclusion: In a randomized double-blind placebo-controlled study, we found that FMT changed gut microbiota in IBS patients. But patients in the placebo group experienced greater symptom relief compared to the FMT-group. The gut microbiota is not enough to obtain clinical improvement in IBS. However, different study designs and larger studies are required to examine the role of FMT in IBS.

Disclosure: Nothing to disclose
analytical retrospective cohort study on all patients (178) with a distal pancreatectomy. The end point was clinical success of endoscopic treatment defined as a complete resolution of POPF discharge or fluid collection (PFC) or size < 2 cm, with association of symptoms resolution, without the need for percutaneous drainage or surgery. Secondary endpoints were technical success (feasibility and efficacy of stent placement), complication rate of endoscopic procedures, and reintervention rate. Categorical variables were compared using χ² test. Normally distributed continuous variables were analyzed by Student t-test and non-normally distributed variables by the Mann-Whitney U-test. Patients were divided in 3 groups (ERCP only, EUS drainage only, both EUS and ERCP).

Results: Out of 173 surgical patients, 58 POPF grade B and C were treated by both procedures (n = 31, 53.4%), EUS alone (n = 13, 22.4%) or both procedures (n = 14, 24.1%). There was a significant shift from ERCP alone (100% of cases between 2000-2005) to EUS alone and combined with ERCP (23% 2006-2010, and 48% 2011-2016). Technical success rates were similar in all groups (87%-100%). Clinical success in patients treated by ERCP only was 64.5% (20/31) and as high as 96.3% (26/27) in patients in whom EUS was performed at any points during endoscopic treatment (p = 0.003). The overall all re-intervention rate was 44.8%, significantly lower when EUS was part of the treatments (20 and 23% vs. 55%, p < 0.05). The complication rates in the ERCP, EUS and ERCP+EUS groups were respectively 20% (n = 6/30), 30.8% (n = 4/13) and 0% (p = 0.346), with a decrease to only 2 AE in the last 5 years.

Conclusion: Endoscopic treatment was highly successful in treating POPF after distal pancreatectomy, with a significantly better clinical success rate of EUS drainage resulting in less reinerventions when needed. We therefore suggest considering EUS as a primary approach, reserving ERCP for cases with pancreatic ductal strictures or inaccessible post-operative collections or fistulas.

OP039 TECHNICAL ISSUES DURING EUS-GUIDED PLACEMENT OF LUMEN APPOSING METAL STENTS: DEFINITION AND CLASSIFICATION, INCIDENCE AND RISK FACTORS, ENDOSCOPIC MANAGEMENT AND EFFECT ON ENDOSCOPIC OUTCOMES

Hospital Universitario Río Hortega, Gastroenterology, Valladolid, Spain

Contact E-Mail Address: s.sevilla.ribota@gmail.com

Introduction: Lumen Apposing Metal Stents (LAMS) have been recently introduced into clinical practice. A variety of Technical Issues (TIs) can appear during LAMS placement but we lack a common terminology to address them and their consequences on clinical outcomes are unknown.

Aims and Methods: We define TI as any alteration in the normal sequence of LAMS placement (TI is not synonymous with adverse event). Consecutive patients undergoing an endoscopic procedure which included the placement of a transmural LAMS between May 2011 and June 2017 in a single tertiary center were included (table 1). Data were prospectively collected and retrospectively analyzed. We propose a novel classification of TIs, categorized in access failure, liberation failures, misplacements and dislodgment. We analyzed their rates, risk factors, endoscopic management and its effect on clinical outcomes.

Results: A total of 298 procedures (47.4% pancreatic fluid collections, 33.5% pancreato-biliary drainages including gallbladder drainages, 13.8% enteric anastomoses, 5.1% others) were analyzed. TI occurred in 27% of them, founding a significant higher rate in technical (99.5% vs 52.6%, p < 0.001), procedural (100% vs 82.1%, p < 0.001) and clinical success (88% vs 77.9%, p = 0.03) when compared with procedures without TIs. Distal (25.6%) and proximal flange misplacements (17.9%) and complete liberation failures (17.9%) were the most frequently encountered TIs. Forceps repositioning, placement of a new LAMS or another through-the-LAMS stent were the most frequent rescued techniques. 13 (16.7%) TIs could not be saved. Enterostomas (OR 3.42 (1.22-9.62) and malignant disease (OR 3.32 (1.05-10.56)) were risk factors associated to the development of TIs on multivariable analysis.

Conclusion: Even in expert hands, TIs are frequent during transmural EUS-guided LAMS placement, typically in distal flange misplacement. The knowledge of salvage techniques using other stents makes rescue possible in more than 80% of cases.

2Hospital Universitario Río Horta, Gastroenterology, Valladolid, Spain
3Hospital San Pedro de Alcántara and CIBERehd, Cáceres, Spain
4Hospital Universitario Río Horta, Gastroenterology, Valladolid, Spain

In 7/29 PP cases, spontaneous resolution was observed; 3/29 PP and 3/31 WON were lost on follow-up, 19/19 PP and 10/10 WON underwent on EUS-guided stent placement, with 100% technical success. Time of procedure per stents as follows: Hot-AXIOS™ 5 (4-6) min, NAGI™ 19 (18-22) min, SPAXUS™ 20 (18-22) min (p = 0.01). In PP cases, a bleeding episode occurred 48 hours after a Hot-AXIOS™ placement (p = 0.58). In WON cases, an obstruction was reported with a Hot-AXIOS™, and a bleeding episode occurred 48 hours after a NAGI™ placement (p = 0.69). Both bleeding events required surgical management. Overall reintervention rate was 10% (3/29) with no reports from plastic stent cases. Overall 30-day mortality was 0%. All stents were finally removed. On this series, none of the cases needed percutaneous drainage. Overall median time from stent placement to complete drainage & removal was 8 (1-200) weeks. Overall median longest follow-up time was 41 (8-120) weeks. 3 cases (2 SPAXUS™, 1 NAGI™) cannot be released due to device failure, and no cases of Hot-AXIOS™ or plastic stent.

Conclusion: Neither stent material nor trademark present a significant impact on clinical outcomes, surgical and adverse events rate was 10% (3/29) with Hot-Axios™ seems to be more practical and faster for placement.

Contact E-Mail Address: amy.tyberg@gmail.com

Introduction: Endoscopic ultrasound guided gastroenterostomy (EUS-GE) is a minimally invasive option for patients with gastric outlet obstruction. It involves creating a gastroenterostomy fistula via EUS and deploying a lumen-apposing metal stent (LAMS) across the fistulous tract. It is a technically challenging procedure requiring combined intraluminal and EUS approaches.

The aim of this study was to determine the learning curve for EUS-GE.

Aims and Methods: Consecutive patients undergoing EUS-GE by a single operator were included from a prospective registry from Aug 2014 to Oct 2017. Data were collected at a median follow-up of 390 days. Non-linear regression and CUSUM analyses were conducted for the learning curve. Clinical success was defined as tolerating a diet.

Results: A total of 103 patients with a median age of 76.1 years (IQR: 61.3–84.3), 58 males, were included. Most frequent diagnoses were pancreatic adenocarcinoma (56.3%), ampulloma (10.7%), GOO and biliary obstruction were treated within the same week in 39/103 patients. Most biliary obstructions were distal (93/103). Initial management was performed with transluminal stenting in 69/103 patients and EUS-D in 34/103 (20 cholecodochoduodenostomies, 13 hepaticogastrostomies, 1 gallbladder drainage). Technical success was achieved in all patients undergoing EUS-D and in 67/69 of the transpapillary drainage group; clinical success was reached in 88.5% EUS-Ds and in 95.6% transpapillary drainages. Duodenal strictures were mostly Mutaginous types I (48.5%) and II (49.5%). GOO score at the time of treatment was ≤ 3 in 87.9% of cases. Initial management was performed with intraluminal SEMS in 100/103 cases and with EUS-GJ in 3 patients. Technical success was achieved in 96.8% and clinical success in 97.5%. Thus, initial management included intraluminal duodenal and biliary stents in 67/103 (65.1%) and EUS-D with intraluminal duodenal stents in 33/103 (32%). Follow-up was available in 89 patients, with a median time of 247 days (91-547), 60% of patients had 64+ follow-up, 4.4% completed the study period and 25% were lost after a median follow-up of 147 days (55-248). We observed a total of 79 biliary events (median 0 events/patients, IQR 0–1). Obstructive jaundice without cholangitis was the most common event (34/79) followed by cholangitis with and without hyperbilirubinemia (14/79). Biliary events were collected. Non-linear regression and CUSUM analyses was conducted for the learning curve. Clinical success was defined as tolerating a diet.

Conclusion: The role of EUS-guided transmural approaches in malignant biliary obstruction and GOO is expanding, but further data are needed before proposing management bundles. Our data suggest EUS-D reduces the need for further endoscopic procedures during follow-up, while EUS-GJ is being increasingly employed.

Introduction: The omega-3 polyunsaturated fatty acid (PUFA) eicosapentaenoic acid (EPA) and aspirin both have proof-of-concept for colorectal cancer (CRC) chemoprevention, aligned with an excellent safety profile.

Aims and Methods: We performed a randomised, blinded, placebo-controlled, 2×2 factorial trial to determine the effects of EPA and aspirin on preventing colorectal adenomas. We also assessed the safety and tolerability of EPA, in free fatty acid (FFA) or tri-gluceryl (TG) form, and aspirin. NHS Bowel Cancer Screening Programme (BCSP) patients (aged 55-73) identified as ‘high risk’ (≥5 small ≤10mm colorectal adenomas; or ≥3 colorectal adenomas, if one ≤10mm) at screening colonoscopy were randomly allocated to receive 99%EPA-FFA 2g or 90%EPA-TG 2780mg (equivalent to 2g FFA) daily, or identical placebo capsules; AND aspirin 300 mg daily, or an identical placebo

Results:
- There was no evidence of any difference in ADR between EPA users (62%) and non-users (61%) (risk difference [RD] -0.6% [-8.5, 7.2]). There was no evidence of an effect on advanced ADR among high-risk individuals (EPA vs. placebo: 18% vs. 20% [RD -1.5% [-4.7, 1.8]]).
- No significant effect was observed on the number of polyps identified. There was no evidence of any difference in ADR at between EPA users (62%) and non-users (61%) (risk difference [RD] -0.9% [95% CI -8.8, 6.9]). There was no evidence of an effect on advanced ADR of either EPA (RD -0.6% [-4.4, 3.1]) or aspirin (RD -0.3% [-4.1, 3.5]).

Conclusion: Neither EPA nor aspirin treatment was associated with a reduction in CRC, but both agents displayed evidence of chemopreventive efficacy, based on adenoma number reduction, which was adenoma type- and location-specific, and is compatible with the known anti-(right-sided) CRC activity of aspirin. Best use of EPA and aspirin may need a precision medicine approach to adenoma recurrence based on colorectal adenoma sub-types. ISRCTN59526847

Disclosure: This project was funded by the EME Programme, an MRC and NIHR partnership. The views expressed in this publication are those of the author(s) and not necessarily those of the MRC, NHS, NIHR or the DoH. MH has received an unretracted scientific grant for another project and also conference travel funding from SLA Pharma AG. MAH has provided paid consultancy for Bayer AG and Theris Pharma.
Aims and Methods: We collected clinical, endoscopic and histopathology data at index colonoscopy and we included both grown and stable lesions. Of the 19 endoscopically correctly diagnosed T1 CRCs, 17 (89.5%) were directly endoscopically resected. There were no correctly diagnosed T1 CRCs that were regressed after a surveillance interval of 3 years. Based on volumetric change, polyps were classified as having 30% regression (PCCRC-3yr), 30% growth (PCCRC-3yr), stable (PCCRC-3yr), or regressed (PCCRC-3yr) or regressed (PCCRC-3yr) or regressed (PCCRC-3yr). All samples were MMR proficient. No relation between growth and CIMP was observed. Based on the molecular definition of having ≥2 CAEs, 9% of all lesions were classified as being at high risk of progression. These lesions included both grown and stable lesions.

Conclusion: Molecular classification, together with adenoma to carcinoma progression are more frequent in growing polyps. The observation that high-risk lesions remained stable and grew, but not amongst regressing polyps, is relevant for screening and surveillance strategies.
Of the 78 endoscopically not as such recognised T1 CRCs, 36 T1 CRCs (46.2%) were resected endoscopically and had been followed up accordingly. Post-resection surveillance guidelines, 2 lesions showed recurrence within 3 years. (Table 1). 34 endoscopically not as such recognised T1 CRCs (45.6%) underwent surgery after an initial attempt at endoscopic resection. Histopathology of the resection specimen showed no residual submucosal invasion in 16 cases (47.1%). The remaining 8 endoscopically not as such recognised T1 CRCs (10.3%) were directly referred for surgery, because these lesions were too difficult to resect endoscopically due to their size and location. Logistic regression analysis showed that distant location (OR 3.83, 95% CI: 2.03–7.25), non-pedunculated shape (OR 2.03, 95% CI: 1.26–3.27) and estimated CRC based on microscopc appearance (OR 4.90, 95% CI: 2.11–11.35) were independent risk factors for submucosal invasion. Conclusion: Approximately 80% of the T1 CRCs in our national CRC screening program are not recognised as early CRCs. Uncertainty about diagnosis may lead to additional colonoscopies, delay in surgery and surgical over-treatment. Improvement in the recognition and treatment of early CRC is needed to further optimize the outcomes of our national CRC screening program.

Introduction: Cholestasis is a common feature of different cholangiopathies such as primary biliary cirrhosis (PBC). Cholestasis causes liver inflammation and induces centrilobular hepatocyte death, thereby inducing ductular reaction and activation of non-parenchymal liver cells [i.e. kupffer cells (KC) and hepatic stellate cells (HSC)] that ultimately result in biliary fibrosis. Liver injury leads to alterations in the intestine epithelial barrier, enabling the translocation of bacterial components from the gut via the portal vein. In the liver, these bacterial components bind to toll-like receptors (TLRs) expressed in KC and HSC promoting inflammation and progression of the wound-healing response. The triggering receptor expressed on myeloid cells 2 (TREM2) is an anti-inflammatory receptor that inhibits TLR-mediated signalling.

Aims and Methods: This study aims to evaluate the role of TREM2 in cholestasis. With this purpose, TREM2 expression was analyzed in the liver of PBC and PSC patients and normal controls. Wild type (WT) and Trem2-/- knock out (Trem2-/-) mice were subjected to bile duct ligation (BDL), or sham, for 7 days. Thereafter, sera were collected for the analysis of biochemical markers and livers were obtained for further histological and gene expression analysis. In vitro, KC’s were wounded from WT and Trem2-/- mice, treated with lipopolysaccharide (LPS) and cytokine and chemokine expression was assessed.

Results: TREM2 expression is upregulated in the liver of PBC and PSC patients as compared to healthy controls; this receptor was also upregulated in a BDL based model of murine cholestasis. After BDL, Trem2-/- mice showed exacerbated liver injury with increased hepatocyte necrosis and immune-cell infiltration compared to WT, as assessed by H&E staining. This was accompanied by augmented expression levels of cholangioyte (Cx-7 and Cx-19) and proliferation markers (Ki67 and PCNA), indicating that Trem-2-/-; animals suffered exacerbated ductular reaction. Likewise, Colta1 and α-Sma mRNA levels revealed enhanced fibrogenesis in Trem2-/-; mice compared to WT after BDL. In addition, the expression of proinflammatory cytokines (Il-6 and Tnfα) and chemokines (Mcp-1 and Cxcl1) were upregulated in these mice. The number of neutrophils infiltrating the liver was also increased in Trem2-/-; mice. LPS-treated Trem2-/-; KC displayed increased expression of pro-inflammatory (Il-6, Il-1B and Cxcl2), but not pro-fibrogenic (Ccl4) cytokines. In addition, Trem2-/-; mice showed a higher proliferation of KCs, suggesting an impaired autologous cell-recruitment and/or limited KC apoptosis.

Conclusion: TREM2 is overexpressed in the livers of PBC and PSC patients and during experimental cholestasis in mice. This receptor negatively regulates TLR4-mediated pro-inflammatory cytokine expression in KC, thereby protecting the liver from cholestatic injury in mice.

Introduction: Inflammatory macrophages play a critical role in liver inflammation. Hepatocellular damage, instigated by viral infections, alcohol abuse or metabolic syndrome, results in the recruitment and activation of inflammatory cells mainly macrophages in the liver. The inflammatory macrophages initiates the process of liver injury progression from liver fibrosis to cirrhosis and hepatocellular carcinoma. Therefore, selective targeted inhibition of the inflammatory macrophages would be a promising approach to attenuate liver inflammation or inflammatory liver diseases. We identified CD6 receptor as a prospective target for pro-inflammatory macrophages.
Aims and Methods: In this study, we developed a novel delivery system i.e CD64-targeted EP to achieve M1-specific uptake and to selectively deliver anti-inflammatory drugs to inhibit M1 inflammatory macrophages thereby ameliorating liver inflammation. Specificity of CD64 receptor was evaluated in vitro in murine and human macrophages and in vitro in CCL4-induced acute liver inflammation mouse model. Novel CD64 targeting peptide was designed and CD64 targeting peptide coated liposomes were synthesized, characterized and evaluated for M1-specific uptake in murine and primary human macrophages using FACS. Prednisolone-encapsulated CD64-targeted liposomes were synthesized, characterized and investigated for efficacy in vitro in RAW macrophages, human THP1 monocytes, primary bone marrow derived macrophages (BMDMs), primary human monocytes, primary human Kupffer cells, and in vivo in acute CCL4-induced liver injury mouse model.

Results: Significant up-regulation of CD64 receptor was observed in murine and human LPS- and IFN-α-treated primary macrophages. CD64-targeted liposomes showed significant reduction in M1-specific inflammatory markers (i.e. iNOS, IL-6, IL-1β and TNFα) in vitro in RAW macrophages, human THP1 monocytes, primary murine BMDMs, primary human monocytes and primary human Kupffer cells. In vivo, prednisolone-encapsulated targeted liposomes demonstrated substantial liver uptake, highly significant attenuation of acute liver inflammation and fibrotic parameters as compared to free prednisolone and non-targeted liposomes.

Conclusion: This study presents a novel strategy to selectively target M1 macrophages therefore holds great promise for diagnosis and therapeutic treatment of liver fibrosis and inflammatory liver diseases.

OP051 IMPACT OF ELECTRICAL PULSE CUT MODE DURING ENDOSCOPIC PAPILLECTOMY: A PROSPECTIVE MULTICENTER RANDOMIZED CLINICAL TRIAL

E. Iwasaki1, T. Ito2, K. Minami1, K. Yamamoto1, S. Tsujii1, S. Fukuhara1, T. Kanan2

1Keio University School of Medicine, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Tokyo, Japan
2Tokyo Medical University, Gastroenterology and Hepatology, Tokyo, Japan

Aim: To compare the outcomes of endoscopic papillotomy (EP) using two different cutting modes (Endocut vs. Autocut) during EP, in terms of immediate bleeding and delayed adverse events.

Methods: We conducted a prospective, multicenter, randomized, single blind, parallel group, controlled clinical trial in patients with ampullary adenoma who were undergoing EP. Randomization was performed using a computer-generated randomization list. After EP, patients were randomized to undergo either EP with “Endocut” (EP-E) using a combined monopolar and bipolar stock tip or EP with “Autocut” (EP-A) with the same stock tip. The primary outcome was a composite of immediate bleeding and delayed adverse events at the time of the clinical follow-up assessment. Secondary endpoints were the time of follow-up, the rate of delayed bleeding, and the rate of delayed adverse events.

Results: From October 2016 to August 2018, 91 patients were randomized, 46 for EP-E and 45 for EP-A. The median age was 72 years (range 26 to 88). There were no significant differences between groups for age, gender, history of upper gastrointestinal bleeding, body mass index, and indication for EP. No significant difference was observed in the rate of immediate bleeding between groups (p = 0.44). Of the 91 patients, 80 (88%) had complete data. In the EP-A group, 8 patients (26.7%; 7 mild, 1 moderate) had acute liver injury that required hospital admission. In the EP-E group, the incidence of acute liver injury was 9 (30.0%; 8 mild, 1 moderate). The primary outcome did not differ between groups (p = 0.02). There were no cases of delayed bleeding and another adverse event were secondary endpoints.

Conclusion: EP-E mode demonstrated a trend toward higher success rate for EP (p = 0.02). However, the rate of delayed bleeding and delayed adverse events were similar between groups. EP-E mode therefore requires further study to confirm the efficacy and safety.

OP052 LUMEN-APPOSING METAL STENTS (LAMS) FOR PANCREATIC FLUID COLLECTIONS: NEW INSTRUMENTS ARE SAFE AND ASSOCIATED WITH A LOW RATE OF DELAYED ADVERSE EVENTS AT THE TIME OF CLINICAL FOLLOW-UP: A MULTICENTER RETROSPECTIVE ANALYSIS

D. Yang1, Y. Peribam2, T. Kerdspirirat1, A. Prabhu1, A. Manvar1, S. Hoc1, D. Punn1, R. Kewsani1, D. Shah1, A. Wang1, E. Quintero1, J. Buscaglia1, J. Storms1, H. Alasian1, P. Dragnich1, A. Siddiqui2

1University of Florida, Division of Gastroenterology and Hepatology, Gainesville, United States
2University of Florida, Gastroenterology, Gainesville, United States

Aims and Methods: Evaluate clinical outcomes at the time of follow-up imaging and endoscopy after LAMS insertion for symptomatic PFC. Multicenter retrospective analysis of consecutive patients with EUS-guided LAMS placement for symptomatic PFC from January 2016 to December 2018.

Main outcomes included resolution of the PFC on follow-up imaging, and findings on follow-up endoscopy after initial LAMS placement, including the rate of adverse events (e.g. delayed bleeding, stent occlusion/migration, buried stent syndrome).

Results: A total of 122 patients (mean age 51 years; 68% male) underwent successful LAMS insertion for 56 WONs (88%) and 55 PPs (95%). The mean size of the PFC was 10.6 cm. Resolution of PFC on cross-sectional imaging was significantly higher for PP (96%; 50 of 52 patients) vs. WON (62%; 34 of 54 patients) at a median of 4 weeks after LAMS insertion (p = 0.001). There were no cases of delayed bleeding. There were no patients lost to follow-up. Size of PFC, diameter of LAMS (10 mm vs 15 mm), additional stents through LAMS (yes vs no), and debriement (yes vs no) were not associated with the likelihood of stent occlusion seen on follow-up endoscopy on multivariate analysis.

Conclusion: EUS-guided LAMS placement for PFC is safe, with serious adverse events encountered at the time of clinical follow-up and delayed adverse events. The rate of PFC resolution on imaging at a median of 4 weeks after LAMS insertion was significantly lower for WON vs. PP. Future large prospective studies are needed to better define the course of PFCs and optimize management protocol for patients with PFC treated with LAMS.

OP053 OPTIMIZING OUTCOMES OF SINGLE OPERATOR CHOLANGIOSCOPY (SOC)-GUIDED BIOPSES: RESULTS OF A RANDOMIZED TRIAL

J.Y. Bang1, A. Navaneethan1, M. Hasan1, K. Krall1, R. Hawes1, S.S. Varadarajulu1,2,3,4,5

1Florida Hospital, Center for Interventional Endoscopy, Orlando, United States
2University of Florida, Division of Gastroenterology and Hepatology, Gainesville, United States
3University Of Florida, Gainesville, FL, United States
4Montefiore Medical Center, New York, United States
5Thomas Jefferson University Hospital, Philadelphia, United States

Aims and Methods: The aim was to determine the optimal method of specimen processing and to identify the number of biopsies required to establish a definitive diagnosis in patients undergoing SOC-guided biopsies. Patients with IBDS and presence of indeterminate bile duct strictures (IBDS) were randomized at ERCP to undergo specimen processing at single operator cholangioscopy (SOC).

Main outcomes were to compare the operating characteristics of onsite versus offsite specimen processing techniques. Secondary outcome measure was to determine the number of biopsies needed to establish definitive diagnosis. Final diagnosis was established at surgery or a minimum clinical follow-up of 12 months.

Results: 62 patients were randomized: onsite = 32, offsite = 30. Location of stricture was common bile duct (n = 19), common hepatic duct (n = 16), hilum (n = 18) and intrahepatic ducts (n = 9). Final diagnosis was benign disease in
35 and malignancy in 27. There was no significant difference in diagnostic accuracy (93.8 vs. 90.0%, p = 0.67), sensitivity (85.7 vs. 76.9%, p = 0.36), specificity (100 vs. 100%, p = 0.99), positive predictive value (100 vs. 100%, p = 0.99) or negative predictive value (90.0 vs. 85.0%, p = 0.99) between the on-site versus off-site cohorts, respectively. A diagnosis was established with a median of 1 biopsy (range 1-3) in the on-site cohort; false positives were encountered in 1 patient and false negatives in 2. The diagnostic accuracy was identical (90.0%) whether patients underwent 3 or 4 biopsies in the off-site cohort; false negatives were encountered in 3 patients.

Conclusions: For centers without onsite cytopathology support, performing three SOC-guided biopsies of the biliary stricture and processing the specimen offsite yields a diagnostic accuracy of 90%.

Disclosure: Shyam Varadarajulu and Robert Hawes are Consultants for Boston Scientific Corporation and Olympus America Inc. All other authors have no disclosures to declare.

OP054 APPLICATIONS OF INTRAOPERATIVE PANCREATOSCOPY FOR THE INVESTIGATION OF PANCREATIC IPMNS

R. Valente1,2, U. Arnelo1,2, R. Pozzi Mucelli3, M.H. Reuterwall1, E. Rangelova1, N. Fagerström1, M. Del Chiaro1

Aims and Methods: To assess the diagnostic yield and clinical impact of intraoperative pancreatoscopy in patients operated for suspect main pancreatic duct involvement IPMNs. It has changed the operative management strategy in 65.2% of patients involving IPMN. It has changed the operative management strategy in 65.2% of patients.

Conclusion: Intraoperative pancreatoscopy is a safe and feasible procedure and provides accurate and secure sampling of pathological tissue in the remnant pancreas.

Disclosure: Effective and safe alternative to PTBD after failed ERP, which can be performed under conscious sedation, often in the outpatient setting. Our technical success rate is comparable to published series. [3] Adverse event rates compared favourably with accepted rates from PTBD. [1] Experience and improved instruments should lead to further improved results. Definitive prospective, randomised studies are needed to compare outcomes for percutaneous versus EUS-guided drainage.

References
remaining indications, EUS-D was performed in 32/870 (3.7%) procedures, p < 0.001. 931 follow-up procedures were performed in 352 patients. Overall, the proportion of ERCPs among follow-up procedures was 85.7%, while ETCGs accounted for 7.4%, EUS-Ds for 4% and combined procedures for 2.9%.

Conclusion: EUS-D was performed overall in 6.9% of 2205 biliary and pancreatic duct drainage procedures (7.6% referred from high ERCP volume centers), whereas PTBD was required in 0.1%. The EUS-guided approach integrated with ERCP could be an optimal option of drainage at index and follow-up procedures.

Aims and Methods: We here designed 2 decellularization protocols to develop tissue in order to replace and regenerate dysfunctional tissue for improved life quality of the diseased patient but may also provide more sophisticated disease models. Engineering approaches to build human pancreatic tissue resembling acinar, ductal and endocrine tissue have been proposed by the complexity of the pancreas. Human pluripotent stem cells (PSCs) may provide the appropriate bioengineering platform for developmental and biomedical studies due to their capability to differentiate into every cell type in the human body.

Introduction: As one of the largest and most functionally complex organs of the body, the intestine is vulnerable to many disorders, which are burdened by high social costs. Options to investigate these functions with direct relevance to the human condition remain severely limited when using conventional two-dimensional (2D) cell cultures and animal models. The field of tissue engineering has extensively explored the development of engineered human gut as a natural 3D-platform for intestinal bioengineering. This approach yields virtually pure cultures of human pancreatic progenitor cells followed by spontaneous differentiation in a 3D-culture environment to allow acinar ductal commitment (Holwieder, GUT, 2017). These cultures are the basis of the current approach.

Results: We have implemented signals controlling embryonic lineage fate bifurcations to efficiently yield the desired cell types through exclusion of alternate fates. Specifically, we applied signaling molecules and growth factors inducing either acinar or ductal cells, while inhibiting the respective counter lineage with inhibitors. This approach yields virtually pure pancreatic acinar or duct-like cells generated from human PSCs resembling key features of adult human pancreatic counterparts as shown in an established test battery. Thereby, we provide a coherent roadmap to generate the 2 mature exocrine pancreatic cell types, acinar and ductal cells. Finally, we have applied this novel tool box to dissect the cell type of origin of pancreatic cancer.

Conclusion: The innovative model presented gives novel opportunities to study developmental processes in the pancreas and bears the unique chance to dissect the cell type of origin of pancreatic cancer.

**Disclosure:** As one of the largest and most functionally complex organs of the human body, the intestine is vulnerable to many disorders, which are burdened by high social costs. Options to investigate these functions with direct relevance to the human condition remain severely limited when using conventional two-dimensional (2D) cell cultures and animal models. The field of tissue engineering has extensively explored the development of de novo tissue in order to restore diseased phenotype. A major opportunity exists to exploit these natural scaffolds as 3-dimensional (3D) models for the in vitro study of gastrointestinal diseases.

**Aims and Methods:** We here designed 2 decellularization protocols to develop acellular 3D scaffolds from both tubular and small scale cube human gut.

**Results:** The resultant scaffolds showed preservation of extracellular matrix (ECM) protein composition and 3D architecture. Decellularized human gut scaffolds were reseeded with human epithelial colorectal adenocarcinoma cells (Caco-2) and primary human intestinal myofibroblasts for up to 14 days. Engrafted cells showed excellent viability, motility, proliferation and remodeling of ECM. In addition, mRNA expression changed when comparing primary human intestinal myofibroblasts cultured in 2D versus 3D scaffolds. Compared to fibroblasts cultured in 2D, ACTA2 and COL1A1 mRNA expression were significantly downregulated whereas TGF-β1 and MMP-3 expression were increased in 3D-cultured myofibroblasts. Moreover, a long-term treatment with TGF-β1 and PDGF-BB, to mimic a diseased model, induced further gene expression in 3D whereas desensitization towards the stimuli was observed in 2D cell cultures.

**Conclusion:** Our results present 2 innovative and effective protocols for the decellularization of human gut. These human-derived intestinal scaffolds may represent an innovative platform for disease modelling, biomarker discovery and drug testing gastrointestinal fibro-carcinogenic disorders.

**Introduction:** Colorectal cancer (CRC) is the third common cancer and the third leading cause of cancer-related deaths in Western countries. The pathogenesis of CRC is a multi-step and multi-factorial process. Disruption of the gut microbiota has been associated with gastrointestinal diseases such as colorectal cancer [1]. The genus Bifidobacterium is considered an important component of the gastrointestinal microbiota. It has an important role in several aspects of gastrointestinal homeostasis: immunologic, neuro-hormonal, and metabolic. Bifidobacterium animalis subsp. lactis is a well documented probiotic form of Bifidobacterium. Mycoprin-like Amino Acids (MAAs) are low molecular weight amino acids. MAAs are unique components of red seaweeds and seaweed products are known as nutrional supplements in bowel diseases. Bifidobacterium animalis does not produce MAAs. If one could create a Bifidobacterium animalis producing MAAs via genetic engineering, it should exert more potent immuno-stimulatory properties and might become a more potent therapeutic agent in colorectal cancer.

**Aims and Methods:** Absynthetic gene cluster for MAAs has been demonstrated in the enteric cyanobacterium Bifidobacterium animalis subsp. lactis PCC 7937 (Cyano-bacterium) is able to synthesize MAAs [2]. Genome studies identified a combination of genes, YP_324358 (predicted DHQ synthase) and YP_324357 (O-methyl transferase), which were present only in B. animalis subsp. lactis PCC 7937 and missing in other Bifidobacterium species. Anaabaena sp. strain 7120 has been induced to produce MAAs after genomic transfer (YP_324358 and YP_324357) genes from Anaabaena variabilis PCC 7937 [3]. The comparative genome analysis revealed that the Bifidobacterium animalis subsp. Lactis. KLD2S 2.0603 strain has similar whole genome sequence to the BB-12 strain [4]. It seems that Cyano-bacterium is the source of MAAs and we hypothesize that the genes of Cyano-bacterium involved in MAAs biosynthesis could be transferred to the strain Bifidobacterium animalis subsp. lactis BB-12 [5].

- **OP059 bifidobacterium animalis subspecies lactis ENGINEERED TO PRODUCE MYCOPRIN-LIKE AMINO ACIDS IN COLORECTAL CANCER PREVENTION**
Results: Genetically modulated *Bifidobacteria* can modulate the immune system to induce inflammation and increase colonic mucosal stability. More decreased chronic inflammation and increased mucosal stability might have the promoting role in colorectal tumorigenesis at different stages including tumor initiation, promotion, progression and metastasis [6]. Also experimental data reveal the important role of NF-κB in colon tumor cells as well as in the surrounding “cancerous” and reactive microenvironment [7]. It can be predicted that this combination may be more effective in preventing colorectal cancer through NF-κB pathway. Elevated TBARS levels are associated with colon cancer initiation and progression and this combination can prevent cancer formation by lowering TBARS levels [8].

Conclusion: Significant progress has been made in recent years in recognizing the importance of gut microbiota to colorectal cancer. Key findings include the discovery of gut microbiota mechanisms that link the gut microbiome to colorectal cancer, including reduced SCFA production, chronic inflammation, altered transcription factors and the immune response. Creating *Bifidobacteria* species producing MAAs via genetic engineering could result in a bacterium that is more potent in its anti-cancer properties. This probiotic could be used not only as a probiotic, also as a pharmacological agent in CRC.

LONG-TERM EFFICACY AND SAFETY OF ALLOGENEIC BONE MARROW-DERIVED MESENCHYMAL STEM CELLS FOR PERIANAL FISTULAS IN PATIENTS WITH CROHN’S DISEASE: A 4-YEAR FOLLOW-UP STUDY

Introduction: Perianal fistulae are regularly observed in patients with Crohn’s disease. Very few effective treatment options to accomplish closure of the fistula tract have been reported. The results from our dose-finding study (allogeneic bone marrow-derived mesenchymal stromal cell (MSC) therapy for perianal fistulae in Crohn’s disease) showed that local administration of MSCs in perianal fistulizing Crohn’s disease is safe and local injection of 1 x 10^6 MSCs and 3 x 10^6 MSCs is safe and feasible. In the current study we present the 4-year efficacy and safety data of 2 of the 3 dose cohorts.

Aims and Methods: All patients from cohort 1 (2 patients placebo; 5 patients 1 x 10^6 MSCs) and cohort 2 (2 patients placebo; 5 patients 3 x 10^6 MSCs) were invited for evaluation. The patients treated in cohort 3 (2 patients placebo; 5 patients 9 x 10^6 MSCs) will be seen in the next few months. Adverse events were registered and fistula healing (e.g. no fistula drainage) was evaluated. All MSC-treated patients were asked to undergo a pelvic MRI scan.

Results: From both groups of patients treated with MSCs, 4 out of 5 patients were available for long-term follow-up after 4 years. 1 of the patients in cohort 1 died because of an adenocarcinoma of the cecum and 1 patient in cohort 2 was lost to follow-up. With regards to therapy efficacy, fistula closure 4 years after MSC-therapy was observed in 3 out of 4 patients treated with 1 x 10^6 MSCs (75%) and in 3 out of 5 patients treated with 3 x 10^6 MSCs (60%). The single patient with an active fistula never experienced a closed fistula after treatment with MSCs. All 4 placebo-treated patients in cohort 1 and 2, still had draining fistulas at deblinding of the study and were offered post study treatment with MSCs. 2 of these 4 patients were indeed treated, now 2 years ago (both are not included in the current 4-year follow-up study). The 2 placebo-treated patients that denied the post study treatment still have fistula drainage after 4 years follow-up. A total of 6 out of 8 evaluated MSC treated patients were willing to undergo a pelvic MRI in the current 4-year follow-up visit. In all 6 patients, the original perianal fistula tract(s) were still seen on MRI.

Several adverse events were reported both in placebo and in MSC-treated patients. Most of the reported adverse events however are in line with the nature of the underlying disease and immunosuppressive medication (e.g., exacerbation of Crohn’s disease, pneumonia, uveitis). However, in the long-term follow-up in 1 patient treated with 3 x 10^6 MSCs, a superficial lesion in the distal rectum showed the presence of Epstein-Barr virus-associated B-cell lymphoma, a rare but currently occurring disease. This patient is currently being treated with chemotherapy.

Conclusion: After 4 years, 8 of 10 patients treated with 1 x 10^6 or 3 x 10^6 MSCs could be evaluated and 88% of these patients reported the absence of draining fistulas, compared to 0% of the patients treated with placebo after 3 years of follow-up. 2 serious adverse events have been reported in the long-term follow-up, but found not to be directly related to MSC therapy. The results of cohort 3 will become available in the summer of 2018. Our preliminary data show that long-term fistula closure can be achieved with a single MSC treatment. More long-term data are needed to further complete the safety profile of MSC therapy for Crohn’s fistulas.

Introduction: Dental pulp-derived mesenchymal stem cells (DP-MSCs) as a source for regenerative medicine are now the subject of much clinical attention. There are high expectations due to their safety, low tumorigenic risk, and low ethical concerns. Tooth-derived MSCs are known to have a great potential in their proliferation and differentiation capacities, even when compared with bone-marrow-derived MSCs.

Aims and Methods: We aimed to examine the hepatic properties and gene expression patterns of DP-MSC-induced hepatocytes and to investigate the affinity of these cells to liver by using a nude rat model. Dental pulp cells obtained from extracted teeth were cultured under the presence of Activin A, FGF, and then insulin and HGF. Production of liver specific proteins including albumin were extracted teeth were cultured under the presence of Activin A, FGF, and then insulin and HGF. Production of liver specific proteins including albumin were investigated. 3 dimensional cultures were perfused with medium containing 5mM NH4Cl and urea concentration in the eluate was assayed. RT-PCR analysis for the genes that are responsible for the experiments was performed. 38 cells labelled cells (1.51x 10^6) were infused via hepatic artery of nude rats and autoradioluminographic images were taken (Dr. Shirai N, Nenmo Science, Co., Ltd, Tsukuba Institute).

Results: Cells differentiated into polygonal hepatocyte-like cells. Production of human albumin fibrinogen, alanine aminotransferase, and hepaplastin in the culture medium were confirmed. The result of conversion of NH4Cl to urea (Table 1). Mean and SD values from these cells to liver by using a nude rat model. Dental pulp cells obtained from extracted teeth were cultured under the presence of Activin A, FGF, and then insulin and HGF. Production of liver specific proteins including albumin were investigated. 3 dimensional cultures were perfused with medium containing 5mM NH4Cl and urea concentration in the eluate was assayed. RT-PCR analysis for the genes that are responsible for the experiments was performed. 38 cells labelled cells (1.51x 10^6) were infused via hepatic artery of nude rats and autoradioluminographic images were taken (Dr. Shirai N, Nenmo Science, Co., Ltd, Tsukuba Institute).

Table 1.

| Urea (mM) | min | 5 | 10 | 15 | 20 | 30 | Mean | 0.68 | 2.28 | 3.72 | 4.96 | 7.60 | SD 0.08 | 0.13 | 0.13 | 0.15 | 0.20 |

Conclusion: Dental pulp MSC-induced hepatocytes had characteristic functions of mature hepatocytes including the production of liver specific proteins and the presence of urea cycle. Because the cells repopulated in livers of nude rat even 168 hrs after the infusion, this methodological approach with high concordance rate (80%), identified an overall 50% decrease of MP and SP neuronal cell bodies implying a critical loss of the neuronal mass. The 50% neuronal reduction correlated with a variety of symptoms / signs of SD patients. This study indicates that quantitative neuronal abnormalities can be demonstrated in patients with AN histopathology.

OP064 CHARACTERISATION OF A NOVEL JUVENILE ONSET DIABETES (JOD) CELL USING HUMAN PLURIPOTENT STEM CELLS

Introduction: Diabetes represents one of the major burdens in the 21st century with approx. 350 million people affected worldwide. Monogenic diabetes such as juvenile onset insulin-dependent diabetes (JOD) or maturity onset diabetes of the young (MODY) accounts for approximately 1-2% of diabetes cases and results from mutations that primarily reduce β-cell function. The identification of the genetic basis of these diabetes forms has translated into novel avenues of personalized medicine in the diabetes field, but only few of these genes have been identified to date.

Aims and Methods: Based on published data, we hypothesize that a proportion of the genetic contribution to common diabetes (T1D and T2D) may be caused by rare monogenic variants/ mutations missed by the current GWAS strategies targeting common variant. The current project reports on such a novel gene relevant as regulator of human pancreatic islet formation but also as a novel juvenile onset diabetes (JOD) gene. For this purpose a stage-specific genome wide profiling complemented with Chip-seq data in differentiating human embryonic stem cells was used.

Results: In our approach we could show that our gene binds and activates Nkx2.2, Nkx6.1 and Pdx1, all belonging to the core suite of isletogenesis transcription factors. Interestingly, this gene co-occupies the enhancer and promoter regions of the latter genes together with Foxa2, Pdx1 and Gata6. Finally, we enter T1D human embryonic stem cells with previously identified mutations in JOD patients. Directed differentiation studies of these cells showed an altered binding pattern of Nkx2.2, Nkx6.1 and Pdx1 finally leading to reduced amounts of monohormonal b-cells. This reduced target gene binding results from a limited zinc affinity due to the mutation that would be necessary as co-factor for gene binding.

Conclusion: The platform provided allows personalised drug-testing and further sheds light on the mechanism how our JOD gene regulates pancreatic development and leads to diabetes in case of certain mutations in humans.

**Introduction:** While most intestinal epithelial cells (IECs) are rapidly renewed, small intestinal IECs residing at the 4+ position quiesce and thereby reside as long-lived IECs. Those long-lived small intestinal IECs are committed to a secretory lineage function as reserve stem cells upon massive loss of the genuine intestinal stem cell (ISC) pool. However, the existence of a long-lived IEC counterpart in the colon remains uncertain.

**Aims and Methods:** We recently reported a newly developed lineage tracing system for secretory IECs by using the Atoh1-CreER::tdTomato mouse. This approach, which combines lineage tracing of Atoh1 IECs and BrdU-based lineage tracing of Atoh1 IECs, we employed the Atoh1-CreER::tdTomato mice (BrdU Cell Rep, 2018). Using these mice, we performed a pulse-chase experiment combining tdTomato-based lineage tracing of Atoh1 IECs and BrdU-based lineage tracing of Atoh1 IECs was conducted to label the aptitude of the limited number of Atoh1 IECs in each region of the colon. Also, region-specific gene expression was examined by subjecting tdTomatomice cells collected from the proximal or distal colon. To investigate the IEC-intrinsic mechanism required for the maintenance of long-lived Atoh1 IECs, we employed the organoid 3D-culture system. Cell cycle status of organoid IECs derived from different parts of the colon was analyzed by flow cytometry or immunoblotting.

**Results:** A distinct population of Atoh1 IECs in the proximal colon exclusively resided as true stem cells, not by BrdU labeling for over 20 days. These label-retaining Atoh1 IECs were generally post-mitotic, as shown by the BrdU labeling experiment consisting of a 1-month labeling period and a subsequent 3-month chasing period. Microarray analysis of Atoh1 IECs in the proximal colon revealed that they exhibited enhanced expression of genes required to maintain quiescence. Consistently, organoids established from the proximal colon showed increased induction of cell cycle arrest and subsequent reduction of proliferation activity, compared to their distal colon counterpart, by promoting Atoh1 IEC differentiation. In addition, secretion-based lineage tracing of Atoh1 IECs, we employed the organoid 3D-culture system. Cell cycle status of organoid IECs derived from different parts of the colon was analyzed by flow cytometry or immunoblotting. In vitro tolerance analysis of 5-FU-induced DNA damage was examined by real-time cell viability monitoring. Finally, we established an IEC-specific 5-FU-induced mucosal injury model to investigate the reserve stem cell capacity of long-lived secretory IECs in vivo.

**Results:** A distinct population of Atoh1 IECs in the proximal colon exclusively resided as long-lived IECs, not by BrdU labeling for over 20 days. These label-retaining Atoh1 IECs were generally post-mitotic, as shown by the BrdU labeling experiment consisting of a 1-month labeling period and a subsequent 3-month chasing period. Microarray analysis of Atoh1 IECs in the proximal colon revealed that they exhibited enhanced expression of genes required to maintain quiescence. Consistently, organoids established from the proximal colon showed increased induction of cell cycle arrest and subsequent reduction of proliferation activity, compared to their distal colon counterpart, by promoting Atoh1 IEC differentiation. **Introduction:** The interferon-free antiviral therapies (Direct Antiviral Agent, DAA) for hepatitis C virus (HCV) infection have allowed treatment of a larger number of patients, including those with cirrhosis, advanced age and comorbidities. It is known that the annual incidence of hepatocellular carcinoma (HCC) in HCV infected patients increases with the degree of fibrosis and is between 2 and 8%. Meta-analysis on interferon antiviral therapy showed a risk reduction of HCC incidence of more than 70%, irrespective of fibrosis stage, in patients who achieved an SVR. Data on DAA therapy are more controversial. Despite previous studies reported a high incidence of recurrent HCC in patients treated with DAA and in whom HCC was previously treated, this data was not confirmed by subsequent large multicentric studies. Some concerns on higher incidence of de novo HCC after DAA treatment have also been reported.

**Aims and Methods:** The aim of this study was to evaluate which variable are eventually associated to HCC occurrence or recurrence in patients with HCV infection and advanced fibrosis. The study included 297 consecutive HCV patients (M 192/F 105; mean age 60.9±12.1; 54.3% with genotype 1 and 23.8 with genotype 3) with high fibrosis stage detected by transient elastography (81 F3 and 216 F4 sec. Metavaric, 16 of whom had a past history of HCC. The following variables were assessed at baseline: liver stiffness, platelets count, Baveno VI criteria for screening varices (stiffness > 20 Kpa and platelet counts < 150,000/mm³), alphafetoprotein, Child Pugh score, MELD score, presence or absence of esophageal varices, presence or absence of diabetes. All patients received an optimal DAA treatment from April 2015 to May 2017. All treated patients were randomly followed up with a median of 20 months (7-33 months). Chi square analysis for categories variables was used.

**Results:** SVR-12 was achieved in 290 patients (97.6%). 23/297 (7.7 %) patients developed HCC de novo or recurrence during the period of follow-up. Among the variable assessed at univariate analysis, liver stiffness > 20 Kpa and platelet counts < 150,000/mm³ known as Baveno VI criteria for screening varices, may be a useful tool to differentiate patients at greater risk of developing hepatocellular carcinoma after DAA treatment. This risk seems to be further increased by the presence of diabetes. Further studies with a larger population of patients will be needed to confirm this observation.

**Introduction:** Nonalcoholic fatty liver disease (NAFLD) may be associated with sarcopenia, which share risk factors including chronic inflammation, insulin resistance, vitamin D deficiency.

**Aims and Methods:** This study aimed to determine whether sarcopenia is independently associated with NAFLD and advanced fibrosis in a nationally representative sample of US adults. Cross-sectional data from 11,323 participants in the third National Health and Nutrition Examination Survey were analyzed. NAFLD was diagnosed by ultrasonographic hepatic steatosis without evidence of other liver diseases. The presence of advanced fibrosis was determined by the NAFLD fibrosis score. Sarcopenia was defined as skeletal muscle index that was measured by bioelectrical impedance analysis.

**Results:** NAFLD was more common in subjects with sarcopenia than in those without (46.7% vs. 27.5%), which was consistent in analyses stratified by gender, obesity status, and ethnicity. A univariate analysis showed that sarcopenia was associated with NAFLD (odds ratio [OR], 2.31; 95% confidence interval [CI], 2.01–2.64), which remained significant after adjustment for age, gender, ethnicity, metabolic risk factors, and vitamin D deficiency (OR 1.24; 95% CI 1.03–1.48). This finding persisted even after adjustment for c-reactive protein as a marker of chronic inflammation. Furthermore, NAFLD-associated advanced fibrosis was more common in subjects with sarcopenia than in those without (7.8% vs. 1.6%), which was also consistent in analyses stratified by gender, obesity status, and ethnicity. Sarcopenia was associated with NAFLD-associated advanced fibrosis independent of metabolic risk factors, vitamin D deficiency, and chronic inflammation (OR, 1.79; 95% CI, 1.18–2.72). An additional sensitivity analysis was conducted including insulin resistance in the model with similar results.

**Conclusion:** In this nationally representative sample of American adults, sarcopenia was independently associated with increased risk of NAFLD and NAFLD-associated advanced fibrosis independent of well-defined risk factors. Interventions to strengthen muscle mass may present an opportunity to reduce the burden of NAFLD and advanced fibrosis.

**Introduction:** Increased intestinal permeability (IP) has now been considered as a key factor in the pathogenesis of non-alcoholic fatty liver disease (NAFLD) and type 2 diabetes mellitus (T2DM). Given the pivotal role of Gut-Liver Axis in NAFLD pathogenesis, genes involved in the modulation of IP are perfect candidates in exploring SNPs that might significantly impact on fatty liver disease severity.

The aim of our study was to assess whether a single nucleotide polymorphisms (SNP) (rs2542151 G>T) of Protein Tyrosine Phosphatase Non-Receptor Type 2 (PTPN2), known to be involved in regulation of IP, is associated with severity of NAFLD (non-alcoholic steatohepatitis -NASH- and/or liver fibrosis) and type 2 diabetes mellitus.

**Aims and Methods:** We recruited a prospective consecutive cohort of NAFLD cases and healthy controls among Caucasian patients from 2 Italian tertiary care centers. PTPN2 genotype was assessed in both patients and controls. Anthropometrics, clinical data and laboratory data were collected for each patient. In the entire cohort the presence of fibrosis was non-invasively assessed by Fib-4 score. A subgroup of patients underwent liver biopsy. Unconditional multiple logistic regression models were used to investigate the association between selected SNP (rs2542151 G>T), comorbidities and histological severity of liver disease.

**Results:** We enrolled 566 cases (males 64.6%, mean age 45.3± 13.8 years) and 377 controls (males 41.3± 3.1 years). PTPN2 genotype distribution was not significantly different between NAFLD patients and controls. Liver biopsy was available for 345 patients; 198/345 (57.4%) had NASH. In the whole study population, considering a genetic dominant model, the analysis showed that patients with the rs2542151 G>T polymorphism had an increased risk of NASH (OR 1.19 95% CI 1.01-1.41 p = 0.01) independently from age and sex. At a subgroup analysis of patients who underwent liver biopsy, rs2542151 G>T of PTPN2 was associated with the presence of severe steatosis (OR 2.19 95% CI 1.35-3.55 p < 0.01), NASH (OR 1.81 95% CI 1.13-2.90 p = 0.05) and severe fibrosis (OR 2.55 95% CI 1.50-4.33 p < 0.01) independently from age and sex.

**Conclusion:** Our study showed that rs2542151 G>T of PTPN2 is associated with the severity of steatosis, fibrosis and NASH histologically assessed. Furthermore, rs2542151 G>T of PTPN2 is associated with the presence of T2DM in patients affected by NAFLD. These results still suggest that in NAFLD patients an individual genetic susceptibility could play a key pathogenic role on IP impairment and consequent liver disease, to lead to a higher histological severity of fatty liver disease and the presence T2DM.

**Disclosure:** Nothing to disclose

**Introduction:** Large scale, real-life data on the long-term course of liver disease after HCV clearance obtained with DAAs are still scanty, and the separate effects on hepatic and non- hepatic causes of death still unclear.

**Aims and Methods:** Between March 2015 and December 2016, 5,166 patients (mean age 55.7±11.5 years; 3,687 (71.3%) c-Jun and Opn expression co-localized in both, human and murine hepatocytes as well as NPLCs and we therefore wondered whether the increased fibrosis observed in c-Jun+/* mice could be rescued by additional deletion of c-Jun in NPLCs (Jun−/−). Indeed, NASH in c- Jun−/− mice was characterized by reduced liver damage, impaired Opn expression, impaired ductular reaction and subsequently less fibrosis. A comparable phenotype was observed in Opn+/− mice, indicating that the phenotype observed in Jun−/− mice was indeed very likely Opn-dependent.

**Conclusion:** These results suggest that c-Jun exerts cell-type specific functions during NASH pathogenesis: c-Jun expression in hepatocytes promotes hepatocyte survival and protects against the NASH-related DR and fibrosis. In contrast, c-Jun expression in NPLCs rather promotes the DR and subsequent fibrosis by regulating Opn expression.

OP071 BLOOD-BORNE HEV TRANSMISSION: TRANSFUSION-TRANSMITTED HEPATITIS E VIRUS INFECTIONS AND EXPERIENCE WITH ROUTINE HEV SCREENING AT A TERTIARY CENTRE
University Medical Centre Hamburg-Eppendorf, Hamburg, Germany
Contact E-Mail Address: thorvatits@s.uke.de
Introduction: Hepatitis E virus (HEV) infection has become a relevant topic with increasing attention and is a major threat for immunosuppressed patients. Routine HEV testing of blood products has recently been implemented in Great Britain and the Netherlands. The relevance of blood-borne hepatitis E virus (HEV) infections for these patients has been discussed controversially within the last months and still requires further investigations.

Aims and Methods: We report (A) our experience of routine HEV testing of blood products at our center and (B) cases of immunosuppressed patients developing transfusion associated chronic HEV infection.

From 10/2016 onwards all blood donors at the University Hospital Hamburg-Eppendorf were routinely screened for HEV RNA (pools of 24 donations) by PCR using the Roche cobas 6800 (LLOD single: 19 IU/ml; 24 pool: 456 IU/ml). HEV RNA positive blood products were not transfused. All immunosuppressed patients with HEV infection (2011-2017) were retrospectively studied. All blood products given to chronically HEV-infected patients were retrospectively analyzed.

Results: (A) 30/29891 donors (0.1%) were HEV-RNA-positive (median viral load 960 IU/ml), whereas only 3 of them (10%) presented with elevated serum transaminases at time of donation (ALT: 83 U/l, 192 U/l and 101 U/l). Retrospective analysis of all HEV-positive donors revealed that 4 donors with asymptomatic infection had been HEV-viremic for up to 3 months. (B) 37 immunosuppressed patients with HEV infection were identified whereas 11 of these (30%) developed chronic HEV infection. In 4/11 (36%) we were able to confirm HEV-infection by HEV RNA testing in blood donations. 2 of these (50%) acquired chronic HEV infection by plasmapheresis/rituximab as treatment for heart transplant rejection.

Conclusion: Overall incidence of HEV RNA in asymptomatic blood donors in our center was higher than previously reported although most donors had low viral load. However, blood products are a relevant source of HEV-infection in particular for immunosuppressed individuals as 36% of chronic HEV infections were transfusion associated. Therefore routine screening of blood products should be implemented in standard care.

Introduction: Helicobacter pylori (HP) is one of the most successful pathogens in the world, infecting nearly half of the world’s population. Importantly, HP is the biggest risk factor in the development of gastric pathology including gastric atrophy, intestinal metaplasia (IM) and dysplasia, all of which are considered precursor lesions to gastric cancer. Autophagy is a cellular degradation mechanism, the physiological role of which is to recycle cytoplasmic components. A specialized form of autophagy, xenophagy, contributes to clearance of intracellular pathogens. Recently it has been shown that HP may modulate autophagy through activation of the endoplasmic reticulum stress (ER stress) pathway. Our previous studies have shown that a single nucleotide polymorphism (SNP) in the autophagy gene ATG16L1 (rs2241880) modulates intestinal ER stress. The aim of this study was to investigate the role of this SNP in HP-mediated autophagy, ER stress and intestinal metaplasia.

Aims and Methods: DNA (n = 262) was isolated from EDTA blood of a cohort of IM patients (PROREGAL Cohort), and the ATG16L1 SNP (rs2241880) status was determined by PCR-RFLP. ER stress and autophagy experiments were performed with gastric cancer cell line SK-GT-2 and immortalized gastric cell line GES-1. ER stress was induced by tunicamycin. ER stress (GRP78) and autophagy (LC3B) were detected by western blot analysis. HP (ATCC 43504) was cultured on Columbia sheep blood agar and heat-killed before cell stimulation. Antral biopsies were taken from 47 patients with IM of which 23 were actively infected with HP (determined by histology), these same patients were biopsied 1 year after eradication. The other 24 biopsies were from patients IM who have never been infected with HP (determined by serology). Immunofluorescence and confocal microscopy was performed on these biopsies using GRP78 as a marker for ER stress. Positivity was scored using the Allredscore taking the average of 4 high powered fields. Statistical significance was determined by Students t-test.

Results: The minor allele frequency (MAF) of rs2241880 (i.e. the A allele, associated with lower intestinal ER stress levels) was calculated as 0.53 in the IM cohort, which was significantly higher than the reference population (Rotterdam study, MAF 0.45, p = 0.0003). After stimulation with HP, ER stress levels in gastric cell lines were reduced, whereas autophagy was induced, as determined by LC3B1 to LC3B1 conversion. These differences were not observed when cells were stimulated with non-pathogenic E. coli bacteria. Biopsies from patients actively infected with HP showed a reduced amount of GRP78 positivity as compared to uninfected patients (p = 0.0171) and the same patients one year after eradication (p = 0.0006).

Conclusion: These results show that HP upregulates the autophagy pathway and thereby reduces ER-stress in vitro and in vivo. Furthermore we show that a genetic variant of the ATG16L1 gene which causes reduced levels of ER stress is more prevalent in patients who have developed precancerous gastric lesions, suggesting that promotion of autophagy and thereby reduction of ER stress contributes to HP-induced changes of the gastric epithelium.

Introduction: The discovery of H. pylori surpassed the long-held conception of the stomach being a sterile organ that does not contain specific microbiota. Further research has shown that H. pylori is not the only inhabitant of the stomach, and other microorganisms can also colonize it. However, the influence of H. pylori on other members of the gastric microbiota remains poorly understood. Research on the bacterial biodiversity within the stomach in H. pylori-positive versus H. pylori-negative gastric mucosa is still controversial.

Aims and Methods: The aim of the study was to characterize the microbial composition of the gastric mucosa in H. pylori-positive and H. pylori-negative subjects by high-throughput 16S rRNA sequencing. Ten gastric mucosal biopsy samples were obtained for metagenomic analysis. According to the rapid urease test combined with cytology results, 6 H. pylori-positive and 4 H. pylori-negative samples were detected. Total RNA from each sample was extracted, which then was used to synthesize cDNA. This step was needed to detect only the living microorganisms of the stomach. DNA libraries of V3-V4 variable region of the 16S rRNA gene were sequenced on the Illumina MiSeq platform. Trimmed reads were analyzed by the QIIME software to characterize the composition of the microbiota.

Results: There is a significant difference in bacterial composition between H. pylori-positive and H. pylori-negative samples. In case of H. pylori-positive patients, a significant dominance of the Helicobacter genus was found, whereas 2 out of 6 samples represented up to 99% of the total microbiota. In the absence of H. pylori infection the predominance of the Streptococcus genus was observed, as well as the presence of the Rothia, Gemellaceae, Fusobacterium and Neisseria genera, which are usually recognized as the normal gastric microbiota. It is interesting to note that H. pylori occurs in small quantities even in cases when no evidence of H. pylori infection is detected according to the rapid urease test and cytology. It is worth noticing that in 4 samples quite a large number of the Nesterenkonia and Helanmona bacterial genera was found, which are usually isolated from the environment, e.g. soil or marine samples, and have not previously been detected in the human digestive tract. Thereby, their role among the other gastric microbiota representatives needs further study.

Shannon diversity index was calculated to analyze the biodiversity in all studied samples. The biodiversity decreased in all H. pylori-positive samples and was in average three times lower than in H. pylori-negative samples. In case of H. pylori infection the predominance of the Streptococcus genus was observed, as well as the presence of the Rothia, Gemellaceae, Fusobacterium and Neisseria genera, which are usually recognized as the normal gastric microbiota. It is interesting to note that H. pylori occurs in small quantities even in cases when no evidence of H. pylori infection is detected according to the rapid urease test and cytology. It is worth noticing that in 4 samples quite a large number of the Nesterenkonia and Helanmona bacterial genera was found, which are usually isolated from the environment, e.g. soil or marine samples, and have not previously been detected in the human digestive tract. Thereby, their role among the other gastric microbiota representatives needs further study.

Conclusion: Microbial composition differs significantly in H. pylori-positive and H. pylori-negative samples; H. pylori tends to prevail in the stomach of H. pylori-positive patients. Bacterial biodiversity is shown to be decreasing in the presence of H. pylori infection. This allows assuming that H. pylori has some sort of inhibitory effect on other inhabitants of the gastric microbiota.

Disclosure: All authors have declared no conflicts of interest.
OP074 CLINICOPATHOLOGICAL FEATURES OF EPSTEIN-BARR VIRUS-ASSOCIATED GASTRIC CARCINOMA WITH SUBMUCOSAL INVASION

Introduction: The frequencies of lymph node metastasis (LNM) in pT1a and T1b gastric cancer (GC) are 3% and 20%, respectively, namely the majority of them have no LNM. The Cancer Genome Atlas Research Network proposed the concept of molecular phenotype classifying GC into 4 phenotypes including Epstein-Barr virus-CIMP (EBV). The EBV group accounts for 8.8% and is considered to have low prevalence of LNM. This study aimed to evaluate clinicopathological features of submucosal invasive (ptmT1b) GC without lymphovascular invasion to choose lower risk group for LNM from ptT1b GC, for expanding indications of endoscopic submucosal dissection (ESD).

Aims and Methods: 411 pT1b GCs without lymphovascular invasion that underwent gastrectomy between 2009 and 2012 at the Cancer Institute Hospital, were enrolled and retrospectively analyzed. Tissue microarray was made and EBV-encoded RNA in situ hybridization was performed for evaluation of EBV status. Patients’ age, sex, tumor location, macroscopic type, predominant histologic type, tumor diameter, depth of submucosal invasion, the presence of ulceration and the presence of LNM were compared between EBV group and non-EBV group.

Results: The EBV group accounted for 11.4% (47/411). Compared to the non-EBV group, the EBV group was more frequent in men (80.8% vs. 64.8%, p = 0.032), located more frequent in upper third region (44.6% vs 18.1%, p < 0.0001), showed deeper submucosal invasion depth (mean 1200 μm vs 600 μm, p = 0.004), and lower frequency of ulceration (21.2% vs 42.8%, p = 0.004). The predominant histologic type of “carcinoma with lymphoid stroma” was more frequent in EBV group than in non-EBV group (46.6% vs 2.2%, p < 0.0001). No LNM was found in EBV group (0% vs 7.7%, p = 0.059). Compared with lymphoma without lymph vascular invasion showed low prevalence of regional LNM regardless of tumor diameter and the extent of submucosal invasion. This group will be a good candidate to be included curative resection criteria of ESD.

Introduction: FGFR2 (fibroblast growth factor receptor 2) has been reported to be associated with cellular growth and carcinogenesis. However, the mechanism underlying its functional role in gastric cancer (GC) remains elusive. Although it is known to be a potent downstream target of Wnt signaling, the function of FGFR2 in the context of cellular proliferation has not been comprehensively revealed. Thus, the aim of this study was to elucidate the function of FGFR2 in gastric cancer cell lines, and to investigate the potential clinical and prognostic implications.

Aims and Methods: A total of 280 subjects with gastric cancer who underwent EGD in Toyoshima Endoscopy Clinic were enrolled in this study. Genotyping by TaqMan assay and subsequently correlated with COX-2 expression level.

Results: miR-155 and miR-223 expression was strongly dependent on H. pylori infection in gastric mucosa and in short-term view shows a trend towards higher expression level as a result of H. pylori eradication treatment. Daily low-dose aspirin as well as NSAIDs intake did influence the expression both in healthy subjects and in patients. However, regular PPI intake was associated with a substantial reduction of miR-155 expression predominantly in patients with gastric cancer independently of the density of neutrophils and mononuclear cell infiltrates. Furthermore, miR-155 expression was inversely associated with COX-2 levels in subjects without H. pylori infection. Further studies are needed to elucidate the potential clinical and prognostic benefit of PPI-related miR-155 modification.

Introduction: Gastric carcinogenesis is a multistep H. pylori-related process. Deregluation of microRNA (miRNA) expression is one of the crucial contributing events in the progression from chronic inflammation to preneoplastic conditions and gastric cancer. Several miRNAs have been suggested as potential biomarkers for preneoplastic conditions. However, nothing is known regarding the modulating effects of non-steroidal anti-inflammatory drugs (NSAIDs) or proton pump inhibitors (PPI) on the miRNA expression.

Aims and Methods: The aim of this study was to investigate the effect of aspirin, NSAIDs and PPI on the expression of mucosal inflammatory miRNAs (miR-155 and miR-223) in H. pylori-infected and non-infected subjects. The study was performed in 2 cohorts: 1) an interventional study in 20 healthy subjects with and without H. pylori infection (each n = 10), and 2) in prospective case-control observational study (n = 188). In interventional study, low-dose aspirin (100mg) was given for 7 days and upper GI-endoscopy including histological sample collection was accessed on the days 0, 1, 3, 7, 9 H. pylori-eradicated subjects repeated the protocol following eradication treatment. Patients from the second cohort underwent upper GI endoscopy including histological evaluation, H. pylori testing (incl. cultivation), biopsy collection and were systemically followed for 2 months. To determine the modulating effects of NSAIDs and PPI on the expression of miR-155 and miR-223 levels were assessed in total RNA extracted from the biopsies using TaqMan Assay and subsequently correlated with COX-2 expression level.

Results: miR-155 and miR-223 expression was strongly dependent on H. pylori infection in gastric mucosa and in short-term view shows a trend towards higher expression level as a result of H. pylori eradication treatment. Daily low-dose aspirin as well as NSAIDs intake did influence the expression both in healthy subjects and in patients. However, regular PPI intake was associated with a substantial reduction of miR-155 expression predominantly in patients with gastric cancer independently of the density of neutrophils and mononuclear cell infiltrates. Furthermore, miR-155 expression was inversely associated with COX-2 levels in subjects without H. pylori infection. Further studies are needed to elucidate the potential clinical and prognostic benefit of PPI-related miR-155 modification.

Introduction: In addition to H. pylori virulence, host genetic backgrounds and other environmental factors also exhibit complex interactions in gastric cancer development. Prostate stem cell antigen (PSCA) single nucleotide polymorphism (SNP) and its decreased expression are associated with gastric cancer1. Genetic variation may develop through a multiple step process known as the gastritis-gastric cancer sequence that is triggered by H. pylori infection. Severe gastritis has been proven to be a precursor condition2.

Aims and Methods: Here, we investigated PSCA SNP rs2294008 and PSCA expression of background gastric mucosa in the gastritis-gastric cancer sequence and revealed host-bacterial interactions in the disease pathogenesis. A total of 280 subjects with H. pylori infection and 28 H. pylori-negative controls who underwent EGD in Toyoshina Endoscopy Clinic were enrolled in this study. Genotyping results of 309 H. pylori-negative controls and 2,329 gastric cancer patients analyzed in our previous study3 were used in this study. DNA was purified from peripheral blood leukocytes. mRNA was purified from remaining biopsy tissues from the gastric mucosa of the incisura angularis. Quantitative real-time PCR was conducted. The expression of the actin, beta gene was used for normalization. To grade the neutrophil activity according to the updated Sydney system, we used 2 biopsy specimens from the greater curvature of the corpus and the antrum. We topographically classified the gastritis into 4 categories

**Introduction:** PSC is a chronic inflammatory liver disease leading to strictures in intra- and extrahepatic ducts and finally to cholestasis and secondary biliary cirrhosis. The etiopathogenesis of PSC is unknown [1]. PSC is a premalignant condition associated with high risk for cholangiocarcinoma (CCA) [2,3]. Currently there are no sensitive surrogate markers to predict the risk. High-throughput metabolomics analysis could offer a potential source to identify biomarkers for risk prediction and personalized disease prevention.

**Aims and Methods:** We aimed to discover metabolomics profiles of serum and biliary samples in 1) controls and PSC patients to find new noninvasive markers for screening and diagnosing PSC, 2) PSC patients with non-advanced disease compared to those with advanced disease to assess the disease progression, 3) PSC patients with and without biliary dysplasia or CCA to find more sensitive and specific markers to detect biliary dysplasia and CCA.

The patients (N = 184) were recruited from the PSC registry of Clinic of Gastroenterology; serum and bile samples are collected and stored at -80°C. Samples are extracted using acetonitrile, and analysed using WATERS Acquity UPLC coupled to XEVO-TQ-S QQQ MS for targeted and quantitative metabolomics analysis [4].

**Results:** Model-based analyses (Generalized Estimating Equations) pinpointed 60 metabolites with significant p-values in bile and/or serum after correction for type-I error. In both bile and serum samples, 2-Aminoobutyric acid, Acetic acid, Asymmetric dimethylarginine, Citrulline, Dodecanoylcarnitine, Guanosine, Homocysteine, Inosinic acid, L-Glutamic acid, L-Glutamine, L-Palmitoylcarnitine, L-Tyrosine, Sorbitol, Stearoylcarnitine, Symmetric dimethylarginine, and Tetradecanoylecarnitine showed consistent differences between healthy controls and PSC patients. Of the above except Citrulline, Inosinic acid, L-Glutamine, and Stearoylcarnitine also allowed differentiating between healthy controls and all affected patients (non-advanced PSC, advanced PSC and dysplasia).

In bile samples alone, Adenine, Chenoecysdohyocid acid, Creatine, Creatinine, Cyclic GMP, Glycicyclic acid, Hippuric acid, Hydroxykynurenine, O-Phosphothanolamine, S-Adenosyl-L-Homocysteine, and Tyrocidine acid Tetradecanoylecarnitine showed consistent differences between healthy controls and PSC patients. With the exception of Chenoecysdohyocid acid, and Hippuric acid, all the above also allowed differentiating between healthy controls and all affected persons. Importantly, Cytidine, L-Kynurenine, L-Tyrosine, and Propionylcarnitine, also differentiated between PSC and dysplasia patients. In serum samples alone, 5-Hydroxyindoleacetic acid, Adenosine monophosphate, Carnosine, D-Ribose-5-phosphate, Decanoylcarnitine, Dimethylglycine, Folic acid, Gamma-Glutamylcysteine, L-Asparagine, L-Kynurenine, L-Tryptophan, NAD, Neopterin, Nicotinamide, Nicotinic acid, Normetanephrine, Spermidine, and Xanthosine showed consistent differences between healthy controls and PSC patients. With the exception of L-Tryptophan, and Spermidine, all the above also allowed differentiating between healthy controls and all affected persons.

**Conclusion:** This study detected a consistent group of metabolites characterizing PSC and dysplasia patients in both serum and bile samples. In addition, fluid-specific candidate biomarkers were pinpointed. Of these, alterations in bile L-tyrosine, Cytidine, L-Kynurenine and Propionylcarnitine characterized dysplasia in particular.

**Introduction:** Several animal models are available to study the cystic fibrosis (CF) related pancreatic damage although they have clear limitations. Recently cystic fibrosis transmembrane regulator (CFTR) knockout ferret and pig models have been generated.

**Aims and Methods:** We aimed to characterize the fluid and bicarbonate secretion of CF and wild type (WT) ferret and pig pancreatic ducts. Pancreatic ducts were isolated from newborn CF and WT ferret and pig pancreas. In the ferret model the expression of CFTR was detected by immunohistochemistry and resting pH, buffer capacity and Cl–/HCO3– exchange activity were evaluated by microfluorometry. Fluid secretion of ducts from CF and WT ferrets and pigs were examined by videomicroscopy.

**Results:** Our results indicate that the bicarbonate secretion is significantly decreased in CF ferret ducts compared to WT. Videomicroscopy revealed a significant increase in fluid secretion to HCO3– and to 5m forskolin and 100 μM IBMX stimulation in both WT pig and WT ferret ducts. In CF ferret and pig ducts increases of the fluid secretion were not detected during the stimulation period.

**Conclusion:** Concerning our data, absence of the CFTR can lead to decreased or completely abolished pancreatic ductal fluid secretion. Our interesting results highlights the importance of studying pancreatic ductal secretion of these new CF animal models more closely.

**OP082** THE EFFICACY OF PENTOXIFYLLINE ON ACUTE PANCREATITIS

D. Wanchangool, K. Techathuvanan
Navarajindradhiraj University, Faculty of Medicine Vajira Hospital, Bangkok, Thailand

Contact E-Mail Address: post030@hotmail.com

**Introduction:** Acute pancreatitis is an inflammatory condition that occurs in the pancreatic parenchyma and systemically affects other organs. The first phase of the disease, usually during the first week, is caused from the patient’s systemic inflammatory response elicited by acinar cell injury. During this phase, the severity of acute pancreatitis is directly related to extrapancreatic organ failure, and several intercellular signaling proteins such as tumor necrosis factor-a (TNF-a) are involved. Although there is currently no specific treatment for such condition, recent evidence in animal models showing that the administration of pentoxifylline, a competitive nonselective phosphodiesterase inhibitor, is able to reduce inflammation through TNF-a inhibition. However, its benefit in acute pancreatitis in humans remains unclear.

**Aims and Methods:** We aimed to study clinical outcomes of pentoxifylline in APACHE II score in acute pancreatitis patients at 72 hours after treatment and to study effects of pentoxifylline on inflammatory markers level (i.e., CRP, ESR, procalcitonin, and Interleukin-6).

**Results:** Pentoxifylline did not decrease severity of disease determined by a reduction in APACHE II score and a percent reduction of APACHE II compared with control group (0 vs. 2; p = 0.267 and 0% reduction vs. 3% reduction; p = 0.019). Interestingly, the level of the systemic inflammatory responds syndrome (SIRS) after 72 hours of treatment was significantly lower than those without pentoxifylline. (7.7% vs. 29.2%; p = 0.048).

**Conclusion:** Pentoxifylline is an anti-TNF-a drug that seems to reduce the inflammatory process of early phase of acute pancreatitis, particularly in patients presenting within 24 hours of onset. The overall severity of the disease and clinical benefit was similar to control group. A future study of pentoxifylline is needed to confirm its efficacy.

**Disclosure:** Nothing to disclose.

**OP081** THE SERUM LEVELS OF SERINE PALMITOYLTRANSFERASE LONG-CHAIN SUBUNIT 3 ARE ASSOCIATED WITH NONALCOHOLIC FATTY LIVER DISEASE-RELATED HEPATOCARCINOGENSE

Contact E-Mail Address: k5142477@kadic.jp

**Introduction:** In recent years, the prevalence of nonalcoholic fatty liver disease (NAFLD) has been increasing, and accordingly, the proportion of hepatocellular carcinoma (HCC) patients with a background of NAFLD has also been on the rise. Although it is important to identify patients with HCC among NAFLD patients, a useful biomarker has not yet been established, so its discovery is needed.

**Aims and Methods:** In addition, we compared the serum SPTLC3 levels and the clinical features. In addition, we compared the serum SPTLC3 levels and the clinical features. In addition, we compared the serum SPTLC3 levels and the clinical features. In addition, we compared the serum SPTLC3 levels and the clinical features. In addition, we compared the serum SPTLC3 levels and the clinical features.

**Results:** 47 muscle miRNAs were found to increase from simple steatosis to non-alcoholic steatohepatitis (NASH), including miR-34a (p < 0.05). Concomitantly, expression of SIRT1, a known target of miR-34a, and activation of AMPK, a metabolic SIRT1-mediator, were decreased (p < 0.05). Mitochondrial dynamics dysfunction was evidenced by decreased Mfn2, a mitochondrial fusion protein and increased Drp1, a mitochondrial fission protein (p < 0.05). Activation of the miR-34a/SIRT1/AMPK pathway is essential to impair mitochondrial and mitochondrial dysfunctions in the skeletal muscle of all three NAFLD animal models, as well as in C2C12 cells incubated with PA (p < 0.05). In note, in an alternative in vivo model, we alleviated PA-induced SIRT1/AMPK and mitochondrial deregulation (p < 0.05). Inversely, miR-34a overexpression mimicked PA-induced dysfunction, an effect that was abolished when downstream AMPK was activated (p < 0.05).

**Conclusions:** These results indicate that activation of the miR-34a/SIRT1/AMPK pathway leads to impairments in mitochondrial metabolism in skeletal muscle of NAFLD patients. As the role of miR-34a in global NAFLD pathogenesis keeps expanding, its further exploitation as a putative therapeutic target is warranted. (Gilead Sciences International – Research Scholars Program in Liver Diseases and SFRH/BD/104160/2014, FCT, Portugal).

**Introduction:** Liver fibrosis is known to be a progressive pathological process that results in the accumulation of excess extracellular matrix proteins, ultimately leading to the development of cirrhosis and, at times, hepatocellular carcinoma. BrG1, a core subunit of the SWI/SNF chromatin-remodeling complex, is known to modulate proliferation in the liver and genes regulating extracellular matrix. However, the role of BRG1 in the progression of liver fibrosis is not well understood. This study aimed to investigate the effect of BRG1 on the progression of liver fibrosis.

**Aims and Methods:** A hepatocyte-specific BrG1 knockout mice model was being used by intercross of BrG11/1 and AlbCre single mutant mice on a mixed genetic background. Carbon tetrachloride (CCL4) was injected in order to induce liver fibrosis for 4, 6, and 12 weeks. BrG1 expression was determined by immunohistochemistry. Liver fibrosis was assessed by analysis of liver fibrosis, particularly in patients presenting within 24 hours of onset. The overall severity of the disease and clinical benefit was similar to control group. A future study of pentoxifylline is needed to confirm its efficacy.

**Disclosure:** Nothing to disclose.

**Intervention:** Intramyocellular lipoprotein deposition associates with mitochondrial dysfunction and insulin resistance (IR), constituting a key pathophysiologic event in non-alcoholic fatty liver disease (NAFLD). Our group has previously shown that human muscle IR correlates with NAFLD severity, while microRNAs (miRNAs/miRs), including pro-apoptotic miR-34a, are progressively regulated during disease progression, in both liver tissue and plasma.

**Aims and Methods:** Now, we aimed to investigate the functional role of miRNAs in the skeletal muscle of NAFLD patients modulating local mitochondrial dysfunction and IR and, hence, contributing for development of metabolic syndrome and NAFLD.

Skeletal muscle biopsies were obtained from morbid obese NAFLD patients undergoing bariatric surgery. Muscle RNA was run in TaqMan™ array microRNA cards. qPCR array data was analyzed using the HFePCR package in Bioconductor. C57Bl/6 mice were fed with different NAFLD-inducing diets including a fast food diet for 25 weeks; a choline-deficient, high-fat diet for 14 weeks; and a choline-deficient amino-acid-defined diet for 32 weeks. C2C12 muscle cells were incubated with palmitic acid (PA) in the presence or absence of A-769662, a AMPK specific activator, or upon miR-34a functional modulation.

**Results:** 47 muscle miRNAs were found to increase from simple steatosis to non-alcoholic steatohepatitis (NASH), including miR-34a (p < 0.05). Concomitantly, expression of SIRT1, a known target of miR-34a, and activation of AMPK, a metabolic SIRT1-mediator, were decreased (p < 0.05). Mitochondrial dynamics dysfunction was evidenced by decreased Mfn2, a mitochondrial fusion protein and increased Drp1, a mitochondrial fission protein (p < 0.05). Activation of the miR-34a/SIRT1/AMPK pathway is essential to impair mitochondrial and mitochondrial dysfunctions in the skeletal muscle of all three NAFLD animal models, as well as in C2C12 cells incubated with PA (p < 0.05). In note, in an alternative in vivo model, we alleviated PA-induced SIRT1/AMPK and mitochondrial deregulation (p < 0.05). Inversely, miR-34a overexpression mimicked PA-induced dysfunction, an effect that was abolished when downstream AMPK was activated (p < 0.05).

**Conclusions:** These results indicate that activation of the miR-34a/SIRT1/AMPK pathway leads to impairments in mitochondrial metabolism in skeletal muscle of NAFLD patients. As the role of miR-34a in global NAFLD pathogenesis keeps expanding, its further exploitation as a putative therapeutic target is warranted. (Gilead Sciences International – Research Scholars Program in Liver Diseases and SFRH/BD/104160/2014, FCT, Portugal).

**Disclosure:** Nothing to disclose.
liver-specific knockout mice was decreased compared to wildtype mice. In addition, lesions in Brg1 knockout mice as shown by Sirius red staining and α-SMA staining. Moreover, serum ALT levels were lower in Brg1 liver-specific knockout mice compared to wildtype mice.

Conclusion: We were able to show that hepatocyte-specific Brg1 deletion prevents liver fibrosis after CCl4 injection in mice. We conclude that Brg1 promotes progression of hepatic fibrosis and may, thus, be used as a potential therapeutic target for the treatment of patients with liver fibrosis due to chronic injury.

OP084 - THE EFFICACY OF SCISSOR-TYPE KNIFE IN ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL ESOPHAGEAL CANCER: A MULTI-CENTER RETROSPECTIVE STUDY

M. Esaki1, Y. Hayashi2, H. Ikehara3, T. Horii4, R. Iedijima5, H. Shibuya6, S. Suzuki7, C. Kusano8, A. Hirotada9, T. Gotoda10, M. Moriyama11

Contact E-Mail Address: esaki_saikei@yahoo.co.jp

Introduction: Scissor-type knife was invented as a device for endoscopic submucosal dissection (ESD) for gastrointestinal neoplasms, which enabled to perform ESD-like biopsy procedure. Therefore, ESD with scissor-type knife (ESD-S) is considered as a technically easier procedure than ESD with non-scissor-type knife (ESD-N). However, there are few reports suggesting efficacy of ESD-S by comparing with ESD-N.

Aims and Methods: This study aimed to compare the technical outcomes of ESD-S with those of ESD-N by propensity score matching analysis. Superficial esophageal cancer treated by ESD between October 2015 and March 2018 at 3 hospitals were retrospectively reviewed. Lesions treated by ESD-S (n = 48) and lesions treated by ESD-N (n = 114) were compared. Multivariate analyses and propensity score matching analysis were used to compare the differences in age, gender, tumor size, tumor location, tumor depth, degree of tumor circumference, operator level and traction method use, including factors which were previously reported to affect the outcomes of ESD. Primary outcome was the procedure time during ESD. Secondary outcomes were the rate of en-block complete resection and the rates of complication (perforation/delayed bleeding) among 2 groups.

Results: Before matching, non-experts had a higher rate of selecting scissor-type knife than experts. Propensity score matching analysis created 34 matched pairs. Adjusted comparisons between 2 groups showed a significant difference in procedure time (median; 42.5 min in ESD-C vs 68.5 min in ESD-D, p = 0.014). In addition, they also showed similar treatment outcomes (en-block resection rate: 100% vs 97.1%; complete resection rate: 88.2% vs 82.4%, p = 0.734; perforation during ESD: 0% vs 5.9%, p = 0.493, delayed bleeding: 0% in both groups).

Conclusion: ESD using scissor-type knife achieved shorter procedure time than ESD using non-scissor-type knife without increase of complication. Therefore, scissor-type knife may become one option as an endo-knife of ESD for superficial ESD.

OP085 - FEASIBILITY AND SAFETY OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR ESOPHAGEAL CANCER IN PATIENTS WITH A HISTORY OF ESOPHAGECTOMY OR GASTRECTOMY: A PILOT STUDY

M. Xu1, Y. Chu2, H. Li3, P. Zhou4
Shanghai Zhongshan Hospital, Endoscopy Center, Shanghai, China

Contact E-Mail Address: xumeidong@gmail.com

Introduction: Patients with a history of esophagectomy for gastrectomy may have a higher risk of suffering from esophageal squamous cell carcinoma (ESCC) due to tumor recurrence or reflux of alimentary juice. Early ESCC can be found by endoscopy examination during the follow up in part of patients. Esophagectomy has been viewed as the gold standard for ESCC, however, a second alimentary tract reconstruction is extremely difficult, which remains esophageal replacement surgery, and some of them accepted radiotherapy. No fatal perioperative adverse events were found. 1 patient had bilateral pleural effusion and treated by improvement of respiratory function and antibiotics, without surgery or drainage. 3 patients suffered from stricture and were treated by endoscopic dilation to relieve stenosis.

Conclusion: ESD is found to be safe and technically feasible in treating early ESCC in patients with a history of esophagectomy and gastrectomy. More follow-up data are needed to be analyzed by further studies to prove its efficacy in these groups of patients in a long run.

Introduction: Recurrence of achalasia symptoms after laparoscopic Heller’s myotomy (LHM) occurs in about 10% of patients due to inadequate myotomy or fibrosis at the site of myotomy. Re-operation can be technically challenging with increased perioperative complications and decreased response. POEM is emerging as a less invasive treatment modality for redo-myotomy in such patients. In this study, we compared the outcomes of POEM in patients with and without prior LHM.

Aims and Methods: Achalasia patients who underwent POEM between April 2014 and June 2017 with at least 2-month post-treatment follow-up were included in the study. Patients were categorized as those with prior LHM and those without prior LHM. Patient demographics, pre-treatment and 2 month post-treatment timet barium esophagram (TBE), high resolution esophageal manometry (HREM) and pH study parameters were compared between the 2 groups. All POEM procedures were performed under general anesthesia and with standard steps. Fisher’s exact test and Mann-Whitney U test was used to test the significance of differences for categorical and continuous variables respectively.

Results: A total of 138 patients (No LHM = 109; prior LHM = 29) were included and 53.8% were females. There was no significant difference in the age, gender, prior treatments for achalasia (apart from LHM), pre-treatment Eckardt’s score, length of stay and complication rates in both groups. The length of POEM procedure (110 [91–130] vs. 97.5 [95.9–110.5 minutes]; p = 0.023) and duration of symptomatic achalasia (5 [4–8] vs. 2 [1–6] years; p = 0.002) were significantly longer in the prior LHM group, 2-month post treatment Eckardt’s scores and
HREM parameters improved significantly in both groups. Post-treatment, patients with prior LHM showed improved vision in all the TBE parameters except for height of barium column at 1 minute, which did not change significantly. On comparing pre-treatment TBE and HREM parameters, patients in the no LHM group had smaller width of barium column at 5 minutes and significantly higher basal LES pressure and lower LES integrated relaxation pressure (LES-IRP) as compared to the prior LHM group. All TBE parameters (except, height at 1 cm) improved more significantly in the no LHM group as compared to prior LHM group. Abnormal pH study with increased DeMeester scores (>14.72) was not significantly different in the 2 groups. **Conclusion:** POEM takes longer procedure time but is safe and effective for palliation of symptoms in patients with recurrent symptoms after prior LHM. Clinical improvement reflected by a decrease in Eckardt’s scores is similar in both groups, although objective improvement in TBE parameters are more impressive in patients without prior LHM.

## OP087 Efficacy and safety of endoscopic resection for small submucosal tumors originating from the muscularis mucosae layer in gastric fundus

**Introduction:** Gastrointestinal submucosal tumors (SMTs) are most commonly found in the stomach, as often as 1 in every 300 endoscopies. Small tumors may be asymptomatic or only present with nonspecific gastrointestinal symptoms, and are usually detected incidentally during upper gastrointestinal endoscopy. Recently, as the widespread use of digestive endoscopy and advances in endoscopic ultrasonography (EUS), the diagnostic rate of small SMTs, including gastrointestinal stromal tumors (GISTs) with malignant potential, has been increasing. According to guidelines set by the National Comprehensive Cancer Network (NCCN), surgical referral should be considered for non-metastatic SMTs, including the following: size >2 cm lacking high-risk features upon EUS. Despite this, the high-risk potential to increase the safety of ESD and overcome difficulties in resecting SMTs is crucial. Our aim was to evaluate the efficacy, safety and feasibility of resection for small gastric SMTs using the ESE and EFTR technique in a large series of patients with long-term outcomes.

**Aims and Methods:** In this study, we evaluated the efficacy, safety, and long-term outcomes of ER for small SMTs of the gastric fundus in a large series of patients which were lacked before. 537 consecutive patients with SMTs no more than 2 cm of the gastric fundus originating from the muscularis propria (MP) layer and treated with endoscopic submucosal excavation (ESE) or endoscopic full-thickness resection (EFTR) were included in this retrospective study at Zhongshan Hospital of Fudan University from January 2013 to September 2016. Clinopathological, endoscopic and follow-up data were collected and analyzed.

**Results:** The en bloc resection was achieved in 100% of patients and complete resection was achieved for 530 (98.7%) lesions. Although total rate of complications was 9.3%, serious adverse events only occurred in 3 (0.6%) patients including major pneumoperitoneum, major hydrothorax and bleeding. Unlike larger tumor size and longer procedure time, endoscopic experience had positive impact on decreasing complications. Based on statistical analysis, tumors with greater size, near cardiac and treated by EFTR were the significant contributors to longer operative times. A median follow-up of 32 months was available and all patients were free from local recurrence or distant metastasis during the study period.

**Conclusion:** Although technical difficulties present in gastric fundus, ER is quite effective and safe for resection of small gastric SMTs with high complete resection rate and rare serious adverse events.

**Disclosure:** Nothing to disclose

## OP088 Endoscopic resection via antral submucosal tunneling for safe en bloc removal of tumors in the duodenal bulb

X. Luo, Z. Han, J. Huang, A. Li, Y. Bai, S. Liu
Nanjing Hospital, Gastroenterology, Guangzhou, China

**Contact E-Mail Address:** luoxiaobei63@126.com

**Introduction:** Generally, endoscopic submucosal dissection (ESD) of the duodenal tumor remains less prevalent due to anatomical characteristics of the duodenal bulb, technical difficulties of the procedure, and a high risk of complications including delayed bleeding and perforations which may require invasive surgical intervention [1][2][3].

**Aims and Methods:** Herein, we describe a novel endoscopic technique, endoscopic resection via antral submucosal tunneling (ERAST), for the en bloc removal of tumors in the duodenal bulb. The specific steps of the ERAST are as following.

1. A mucosal incision is made using a Hybrid knife (1-type, ERBE, Germany) approximately 5 cm proximal to the pylorus.
2. A submucosal tunnel extending to the duodenal tumor via the pylorus is then created. To completely expose the tumor, submucosal tunneling following entry into the duodenal bulb is continued until approximately 10 mm distal to the pylorus. Soft coagulation (80 W on effect 4, ERBE, Germany) is recommended for hemostasis in the bulb to prevent potential perforation of the thin duodenal muscularis propria.

**Results:** As shown in Table 1, 4 tumors, independent of their location in the duodenal bulb, were successfully resected by ERAST and 100% en bloc resection was achieved. No major bleeding or perforation occurred during ERAST and no postoperative complications such as delayed bleeding, perforation or hyperpyrexia was observed. Esophagogastroduodenoscopy carried out 2 months after the ERAST revealed that the indicated wound had healed completely without recurrence or biliary reflux and no patients reported any discomfort. Leveraging the use of submucosal tunneling to facilitate endoscopic resection, the endoscopic view enabled by ERAST facilitates recognition of anatomic layers of the thin duodenal wall and hence, demarcation of a clear and safe dissection line above the pylorus. A submucosal tunnel extending to the duodenal tumor via the pylorus is then created. To completely expose the tumor, submucosal tunneling following entry into the duodenal bulb is continued until approximately 10 mm distal to the pylorus. Soft coagulation (80 W on effect 4, ERBE, Germany) is recommended for hemostasis in the bulb to prevent potential perforation of the thin duodenal muscularis propria. Next, a mucosal incision is made from the inner side of the submucosal tunnel towards the duodenal lumen. The circumferential mucosa of the tumor is then incised in a step-by-step manner to remove the tumor en bloc. An endoclip tied with floss is used to extract the tumor out from the duodenum. Finally, the mucosal defect in the bulb and the mucosal incision in the antrum are closed using endoclips (Micro-Tech, Nanjing, China) combined with endoloop (MAJ-254, Olympus). ERAST takes advantage of submucosal tunneling to facilitate tumor resection and has the potential to increase the safety of ESD and overcome difficulties in resecting tumors that are anatomically challenging to access.

In this preliminary study, we evaluated the feasibility and safety of ERAST for the treatment of lesions in the duodenal bulb.

**Conclusion:** In conclusion, our findings suggest that ERAST is feasible and safe for the removal of lesions in the duodenal bulb, particularly for those in challenging anatomical locations. However, further prospective studies with a larger number of cases are warranted to investigate the long-term recurrence rates and potential adverse effects.

**Disclosure:** Nothing to disclose
**OP089 THE POCKET-CREATION METHOD FACILITATES ENDOSCOPIC SUBMUCOSAL DISSECTION OF LARGE SESSILE TUMORS**

**T. Yamashina**

**Introduction:** Large sessile and subpedunculated tumors are frequently associated with severe submucosal fibrosis and retraction of the muscularis (1,2). Therefore, endoscopic en bloc resection by endoscopic submucosal dissection (ESD) is challenging. Pocket-creation sign during endoscopy may be diagnostic since the fibrosis is often benign without tumor invasion and many of these tumors are limited to the mucosa. The pocket-creation method (PCM) provides adequate submucosal traction enabling ESD, even with submucosal fibrosis (3). We previously reported that the PCM facilitates ESD of laterally spreading colorectal tumors, non-granular type, frequently complicated by submucosal fibrosis (4).

**Aims and Methods:** The aim of this study is to assess the utility of PCM to overcome the difficulties caused by even severe fibrosis associated with large sessile and subpedunculated tumors by comparing ESD using the PCM with conventional methods (CM).

A total of 887 colorectal lesions were resected by ESD between April 2010 and June 2016. Of the 109 lesions, 18 were smaller than 20 mm in diameter and one non-neoplastic lesion was excluded. This is a retrospective review of the remaining 90 colorectal large sessile and subpedunculated tumors. Of the 109 lesions, 18 were smaller than 20 mm in diameter and one non-neoplastic lesion was excluded. This is a retrospective review of the remaining 90 colorectal large sessile and subpedunculated tumors in 89 patients. The lesions are divided into PCM (n = 40) and CM groups (n = 50). The primary outcome measure was en-bloc resection rate. Secondary outcome measures included (1) R0 resection (en bloc resection with histologically negative resection margins); (2) complications; (3) dissection time (min); (4) dissection speed (mm²/min).

**Results:** PCM and CM achieved high en bloc resection rates. (PCM, 100% [40/40]; CM, 94% [47/49]; p = 0.05). ESD of 2 lesions in the CM group were stopped during the procedure, 1 after immediate perforation was recognized, and 1 with a deep invasive tumor converted to Endoscopic Mucosal Resection. 1 lesion in the CM group was resected in a piecemeal fashion. Tumor diameters (mm) were similar (median (range), PCM: 30.5 (20-57) vs. CM: 30.5 (20-90), p = 0.77) There were no differences in R0 resection rates (88%, 35.4% vs. 78%, 38.4% vs. 1.0, p = 0.05) or incidence of adverse events (perforation and late delayed bleeding, 5%, 2.0% vs. 1.0, p = 0.50, 0.69). When the PCM was used, the rate of pathologically negative vertical margins (p = 0.04) was significantly greater, dissection time (p = 0.04) shorter and dissection speed (p = 0.02) faster than when CM was used.

**Conclusion:** ESD using PCM increases the rate of negative vertical margins with rapid dissection for the treatment of large colorectal sessile and subpedunculated tumors.

**OP900 EOSINOPHILIC OESOPHAGITIS WITH INFLAMMATORY BOWEL DISEASE: EPIDEMIOLOGY AND OUTCOMES FROM A LARGE POPULATION-BASED ANALYSIS**

B. Limketkal1, E. Bellaguarda2, J.-F. Colombel1

**Introduction:** Eosinophilic oesophagitis (EoE) is an immune-mediated condition that shares some immunological pathways with inflammatory bowel diseases (IBD). Few case reports have suggested an overlap between EoE and IBD, although some studies have suggested that this overlap is rare. The epidemiology and implications of this relationship are unknown.

**Aims and Methods:** The primary objectives of this study were to estimate the prevalence of EoE in IBD and to identify potential adverse outcomes of co-diagnosis. Given the rarity of EoE in IBD, we relied on a very large population-based cohort to maximize the sensitivity and precision of our analyses. All enrollees in the Truven Health MarketScan® Research Database (2007–2016), the largest health claims database in the United States, were included in this study. Patients with EoE, Crohn’s disease (CD), and ulcerative colitis (UC) were identified based on recurrent diagnoses using the International Classification of Diseases 9 and 10 codes. Descriptive analyses were used to estimate the prevalence and characterize the demographics of IBD patients with or without EoE. Cox proportional hazards models were used to compare the longitudinal risk of major adverse outcomes (corticosteroid use, initiation or change in biologic therapy, hospitalization, and abdominal surgery) between IBD patients with and without EoE. Regression models controlled for age, sex, and geographic region.

**Results:** There were 153,232,283 individuals with a median follow-up time of 18 years (interquartile range 0.8 to 3.8). The overall prevalence of EoE was 68.5 per 100,000 individuals. The prevalence rates of EoE were significantly higher in patients with CD (508.0 per 100,000; p < 0.01) and UC (1325.0 per 100,000; p < 0.01) than in the general population. CD and UC patients with EoE were predominantly male (CD: 61.8% vs. 38.2%, p < 0.01; UC: 56.6% vs. 43.4%, p < 0.01) and younger (CD: 33.9 vs. 46.1 years, p < 0.01; UC: 34.1 vs. 48.9 years, p < 0.01) than IBD patients without EoE. For CD patients, EoE was associated with an increased risk of corticosteroid use (adjusted hazard ratio [aHR] 1.16; 95% CI 1.07 to 1.25; p < 0.01) and the initiation or change in biologic therapy (aHR 1.21; 95% CI 1.05 to 1.39; p < 0.01), but not hospitalization or abdominal surgery. For UC patients, EoE was similarly associated with an increased risk of corticosteroid use (aHR 1.26; 95% CI 1.13 to 1.40; p < 0.01) and the initiation or change in biologic therapy (aHR 1.50; 95% CI 1.03 to 2.20; p = 0.04), but not hospitalization or abdominal surgery.

**Conclusion:** In this first population-based study of EoE in IBD, EoE was found significantly more common in younger and male patients. EoE was associated with increased risk of corticosteroid use and biologic therapy, but not hospitalization or abdominal surgery. Given the observed relationship between EoE and IBD, further investigation into the epidemiology and pathophysiology of both diseases may provide insight into shared mechanisms of pathogenesis.

Introduction: Mesenchymal cell therapy is promising for the treatment of perianal CD fistulas refractory to conventional therapy. Autologous adipose-derived stem cells (ADSVF) are a group composed by 16 Sicilian centres which continuously enter in a web based software all clinical data of IBD patients treated with biologics. In the absence of head-to-head trials, there is an unmet need to compare different biologics for the treatment of perianal disease with a PDAI score that passed from 7.3 at baseline at 3.8 at week 48 (40% of remission, 20% of complete response, 20% of partial response) which was achieved in 13 (48%) cases and endoscopic efficacy in 12 (40%) patients. A study evaluating efficacy and safety in the majority of the patients at short term and allow avoiding surgery in almost half the patients at long term. 

Disclosure: Nothing to disclose

Reference: From October 2015 and March 2017, 10 patients were treated by this innovative local treatment (among 10 cc of microfat and about 30 millions of ADSVF viable cells subsequently injected into the soft tissue around the fistula). No serious adverse events have been described. The most frequent side effect was local pain on lipoaspiration site. No case of incisional infection post treatment was described. About 70% of response was found at week 12 (50% of partial response and 20% of remission) and 80% of response at week 48 (40% of remission, 20% of complete response, 20% of partial response). These results were confirmed to significant improvement of quality of life score (p = 0.038).

Conclusion: This first study evaluating co-local administration of ADSVF in association with fat graft appears to be a simple, safe and efficient surgical regenerative therapy for perianal CD fistula refractory to conventional therapy.

Introduction: In the absence of head-to-head trials, there is an unmet need to better understand the effectiveness of different biologics in inflammatory bowel disease (IBD). The Sicilian Network for Inflammatory Bowel Disease (S-NIBD) is a group composed by 16 Sicilian centres which continuously enter in a web based software all clinical data of IBD patients treated with biologics.
Aims and Methods: Data of all incident Crohn’s disease (CD) patients treated with 5-Aminosalicylic acids (5-ASA) during 2013 to January 2014 were extracted from the cohort of SN-IBD. Patients were divided in biologic-naive and non-naïve, and the 2 groups were analyzed singularly. We used a 1-to-2 propensity score matching (2:1) for accounting for the main baseline characteristics in naïve patients, and a 1-to-1 propensity score matching (1:1) for non-naïve patients. Clinical outcomes were evaluated at 12 weeks and 1 year.

Results: 632 patients (735 total treatments) were included. After propensity score matching, 214: 1:IFX: 47 patients were matched for 214:1 non-naïve patients (total treatments: 94; ADA: 47; IFX: 47) were analyzed. Among naïve patients, a clinical benefit was achieved in 175/214 (81.8%) patients treated with ADA and in 84/107 (77.6%) patients treated with IFX (adjusted OR: 1.23, 95% CI 0.95–1.61; p = 0.027). After 12 weeks, 80% of patients treated with ADA and 90% of patients treated with IFX (adjusted OR: 1.10, 95% CI 0.61–1.96, p = 0.766). The rate of adverse events was significantly higher in patient treated with IFX (incidence rate ratio 1.87, 95% CI 1.02–3.43, p = 0.040). Conditional logistic regression model showed that previous surgery (adjusted OR: 0.19, 95% CI 0.04–0.78, p = 0.021), upper GI localization (adjusted OR: 0.20, 95% CI 0.05–0.84, p = 0.028), and fistulizing behavior (adjusted OR: 0.29, 95% CI 0.10–0.87, p = 0.027) were independent risk factors for a reduced rate of clinical benefit at 1 year. Among non-naïve patients, a clinical benefit was achieved in 29/47 (61.7%) patients treated with ADA and in 32/47 (68.1%) patients treated with IFX (adjusted OR: 0.72, 95% CI 0.21–2.44, p = 0.600) at 12 weeks and after 1 year, clinical benefit was achieved in 23/47 (48.9%) patients treated with ADA and in 19/47 (40.4%) patients treated with IFX (adjusted OR: 1.23, 95% CI 0.54–2.86, p = 0.620). The rate of adverse events was significantly higher in patient treated with IFX (incidence rate ratio 2.57, p = 0.009). No prognostic factor of clinical benefit was found among non-naïve patients.

Conclusion: In the first study comparing the clinical effectiveness of ADA and IFX in moderate to severe CD patients via propensity score, there was no significant difference between the 2 drugs, neither in naïve nor in non-naïve patients.

Introduction: The goal of treatment in ulcerative colitis (UC) is to induce clinical response and maintain steroid-free disease remission in the long term. The aim of the present study is to examine how moderately-to-severe UC is currently managed in real-world clinical practice across select Western European countries.

Aims and Methods: Data from the 2017 Adelphi Inflammatory Bowel Disease Specific Programmes (IBD-DSP) were used. The IBD-DSP is a database of patient chart information abstracted by selected gastroenterologists across the European Union Five [EUS]: i.e., France, Germany, Italy, Spain, and the United Kingdom [UK]. Eligible gastroenterologists who agreed to participate were asked to complete patient record forms for the next 7 consecutive eligible adult patients with UC. Only charts from patients with moderate-to-severe UC were included in the analysis (defined as those with documented administration of either an immunomodulator [IM] or a biologic). Treatment usage by line of therapy (defined as the sequential order of treatments after diagnosis) and the percentage of dose escalation was reported using descriptive statistics (mainly percentages).

Results: A total of N = 1191 patient charts were included (France: N = 331, Germany: N = 271, Italy: N = 207, Spain: N = 230, UK: N = 152; 56.5% male; median age at diagnosis (55 years). Patients had been diagnosed for a mean of 4.7 years (SD = 5.9). For those with complete treatment history (N = 1060), 47.1% used 5-ASA/s and/or steroids as their first-line therapy. The remaining 52.9% used either an IM or biologic as first-line therapy (IM without biologic = 27.4%; infliximab [IFX] = 13.3%; adalimumab [ADA] = 9.8%; golimumab [GOL] = 1.3%; vedolizumab [VDZ] = 0.8%). Use of IM therapy (without a biologic) was higher in subsequent lines: second-line = 41.3%, third-line = 38.3%. Similarly, the use of a biologic also increased in second-line (IFX = 19.0%, ADA = 10.4%, GOL = 3.6%, VDZ = 2.4%) and then again in third-line (IFX = 19.9%, ADA = 14.6%, GOL = 4.0%, VDZ = 6.6%). The percentage of patients treated with biologic therapy who were also using a concomitant IM increased over time from first-line to third-line: IFX = 19.9% to 32.0%, ADA = 12.5% to 25.9%, GOL = 7.1% to 20.6%, VDZ = 11.1% to 20.0%. Treatment preferences for patients currently using a biologic therapy, dose escalation during maintenance therapy (i.e., a higher than indicated dose or greater than indicated dosing frequency) was observed as follows: IFX = 39.1%, ADA = 36.1%, VDZ = 30.9%, GOL = 20.8%.

Conclusion: Among patients with UC in the EU5 who go on to use an IM or biologic treatment, many patients use these treatments as their first therapy after diagnosis. Combination therapy with both IM and biologic therapy is also common and increases over the course of the disease. For patients who use biologic therapy, between 27.4% of patients use a higher than indicated dose and/or frequency. These findings suggest a number of patients experience sub-optimal levels of disease control.

Introduction: Barrett’s oesophagus (BO) is a known precursor lesion to oesophageal adenocarcinoma (OAC). All clinical guidelines recommend surveillance and/or treatment of BO patients depending on the severity of the precursor lesion. However, the optimal management strategy for non-dysplastic BO (NDBO) and low-grade dysplasia (LGD) patients remains controversial. Prior modeling studies have reported conflicting results on the management of these patients.

Aims and Methods: We aimed to identify the optimal management strategy for BO patients through a comparative modeling analysis. We used 3 independently developed population-based models from the NCI Cancer Intervention and Surveillance Modeling Network (CISNET). A cohort of 60-year-old US men with 100% smoking and followed until death without surveillance or treatment (natural history). Then, we implemented 78 unique BO management strategies. The strategies varied in (a) LGD management: with or without confirmation of LGD by a repeat endoscopy at 2 months, and surveillance with different intervals or endoscopic treatment; and (b) NDBO management: no surveillance or surveillance with different intervals. In all strategies, patients with high-grade dysplasia received endoscopic treatment. An incremental cost-effectiveness analysis, assuming a willingness-to-pay threshold of $100,000 per quality-adjusted life-year (QALY), determined the optimal strategy using the average results of the 3 models. To assess the robustness of our findings, we also analyzed the separate results of each model and simulated a cohort of US women with BO.

Results: The model’s average OAC incidence in the natural history was 110 (93-120) and the average cost was $5.57 million ($4.5-6.7 million) per 1000 BO patients. Surveillance and/or endoscopic treatment of BO patients prevented 23-37% of OAC cases, but they increased costs to $6.3-17.0 million. Considering cost-effectiveness, all strategies with only surveillance for LGD patients were dominated by those with LGD treatment. Repeated endoscopy to confirm LGD was more cost-effective than strategies without confirmatory endoscopy. The optimal strategy was treatment after confirmation by repeat endoscopy for LGD patients and surveillance every 3 years for NDBO patients.

Conclusion: Our analyses show that endoscopic treatment of patients with LGD is cost-effective, even if only these patients undergo repeat endoscopy to confirm LGD before treatment. The optimal strategy for NDBO patients is surveillance using 3-year intervals in men and 5-year in women.

[Table 1. Optimal management strategy for BO patients]

Disclosure: Nothing to disclose
Aims and Methods: Multicenter study in 9 European centers on patients with biopsy proven neoplastic BE. Following endoscopy (EMR) and a maximum of 5 H-APC sessions was allowed; exclusion ablation for neoplastic BE (LGIN/ HGIN) could be performed at the discretion of the endoscopists for neoplastic BE (LGIN or HGIN) without visible lesions. Primary therapeutic success was defined as one follow-up endoscopy showing normal endoscopic neo-Z-line with negative biopsies.

Results: 130 of 164 included patients (112 male, 18 female, mean age 63.8 years) have completed therapy with 3 month follow-up, 19 were excluded from the therapeutic concept for a variety of reasons. Final diagnoses were mucosal cancer (n = 79), high-grade (HGIN, n = 23), low-grade dysplasia (LGIN n = 26) and normal BE (n = 2). Therapy: Combined resection and ablation (n = 117), exclusion ablation (n = 13). Mean number of H-APC sessions: 2.69 (range 1-5). Short-term treatment outcome: Endoscopic treatment success (normal Z line) was seen in 99 cases, but in 6 cases histopathology showed intestinal metaplasia (minimal residual BE disease) or (n =1) residual cancer. 31 further cases each had either indeterminate endoscopy (minimal residual BE possible) but either negative biopsies (n = 27) or minor residual normal BE on biopsies. Based on histopathologic proof, short-term eradication rates were 89.2% (116/130). Treatment for minor residual BE is currently ongoing in some patients. Immediate complications: bleeding n = 5, post-procedure fever n = 9 and 1 perforation treated conservatively by clipping. Later strictures requiring dilation: n = 5 (5/130 = 3.8 %). In the 12 months follow-up (n = 101 at present), the endpoint of a macroscopically normal Z-Line with negative biopsies was maintained in 88/101 cases (87.1%), with 2 cases included who had indeterminate endoscopy (suggesting minor residual BE) but negative biopsies. Of the 13 cases with positive biopsies (macroscopically visible BE in 2 of them), all had non dysplastic BE. The H-APC for BE ablation appears to be feasible and safe with a short- and mid-term efficacy of close to 90% in this interim analysis; final results of this large prospective study have to be awaited. The comparative value of H-APC to RFA will be assessed in a prospective randomized trial.

Introduction: Cryotherapy has been used for years to eradicate flat dysplastic Barrett’s esophagus (BE), since it may be better tolerated and result in lower strictures rates when compared to heat-based ablation techniques. Cryoballon ablation (CBA) is a new technique comprising a through-the-scope catheter with a conformable balloon that is inflated and cooled using nitrous oxide. Thus far, focal CBA has been promising, but only suitable for treatment of limited BE. The novel swipe CBA (90°-SCBA) covers 90° of the esophageal circumference over 3cm in a single step. The controller software allows for adjustment of the dose (the rate at which the diffuser traverses the 3cm long axis of the balloon catheter while emitting oxygen). 90°-SCBA has been feasible and safe in animal and pre-endoscopy/gastroenterology studies.

Aims and Methods: The aim of this study is to assess feasibility, safety and dose-related efficacy of 90°-SCBA in patients with dysplastic BE. Patients with flat BE (circumferential extent ≤3cm) and low or high-grade dysplasia (LGD/HGD) or residual cancer after endoscopic resection (ER), were enrolled in 5 Dutch BE expert centers. Half of the esophageal circumference was treated, starting with 0.8mm/sec (dose 1). The dose was then escaladed with 1.0mm/sec (6 patients per dose) until the effective dose (ED) was found. ED was defined as the lowest dose resulting in a median BE regression >90% in the absence of dose-related serious adverse events (DR-SEA). ED was subsequently confirmed in a confirmation cohort. DR-SAES included severe pain (VAS > 6) for >7 days or stenosis requiring dilation. Pain (VAS 0-10), dysphagia (0-4) and other adverse events were evaluated at days 0, 1, 7 & 14. Primary outcomes were technical success, 90°-SCBA success and efficacy (BE regression at 8 weeks follow-up (FU) endoscopy assessed by 2 independent endoscopists by systematic comparison of baseline and FU videos).

Disclosure: No conflicts of interest.
Results: In total, 25 patients were included (74% male, median BE C0.5). Baseline pathology was ID (76%), HGD (12%) and adenosinarctinoma (12%). Five patients were treated with ER before inclusion. The 90-SCBA procedure was technically successful in 23 patients (92%). Device malfunctions occurred in 2 other patients (8%) and were resolved with device replacement. No DR-SAEs occurred (Table). BE regression at FU was 78% (IQR 69-86) with 0.7mm/sec (dose 1, N = 6) and 85% (75-95) with 0.7mm/sec (dose 1, N = 6) and 85% (75-95) with 0.7mm/sec (dose 1, N = 6). Age, median (IQR) 67 (52-80) 67 (53-70) 67 (62-71).

Previous EMR, n(%) 1 (17) 3 (43) 1 (8). Median dysphagia score was 0 at all FU timepoints. Conclusion: Our multicenter pilot study suggests that semi-circumferential treatment with 90-SCBA is feasible, safe and well tolerated for eradication of flat dysplastic BE. Results in a median BE regression of 85% in the 19 patients treated at a dose of 0.7mm/sec (ED) and is a promising new modality for endoscopic eradication.

Introduction: Restorative proctocolectomy and ileal pouch-anal anastomosis (IPAA) is the surgical therapy of choice for patients with refractory or complicat- ed ulcerative colitis (UC). Approximately 60% of these patients develop pouch inflammation (pouchitis).

The hypothesis is that pouchitis may occur due to compromise of the epithelial barrier function and exposure of the intestinal immune system to microbial antigens. Increased luminal proteolytic activity was associated with exacerbation of colitis in animal models as well as in patients with inflammatory bowel diseases.

Aims and Methods: We aimed to study whether luminal proteolytic activity is increased in UC patients with pouchitis and what are the functional implications on epithelial barrier function.

FCal supernatants were exposed to fecal supernatants. Epithelial integrity and permeability were determined by measuring trans-electrical epithelial resistance (TEER) and permeability of a 4 kDa FITC-dextran across the monolayers. Immunofluorescence and Western blot were performed on Caco-2 cells to assess for tight junction proteins integrity (ZO-1, occludin) after exposure to fecal supernatants.

Results: Fecal supernatants were obtained from 25 patients: 6 NP, 10 AP and 9 HC participants. Proteolytic activity was determined using FITC-casein florescence assay. Caco-2 cell monolayers were exposed to fecal supernatants. Epithelial integrity and permeability were determined by measuring trans-electrical epithelial resistance (TEER) and permeability of a 4 kDa FITC-dextran across the monolayers. Immunofluorescence and Western blot were performed on Caco-2 cells to assess for tight junction proteins integrity (ZO-1, occludin) after exposure to fecal supernatants.

TO AN IMMUNOSUPPRESSIVE PHENOTYPE

J. Geginat10, M. Vecchi2,11, M. Rescigno1, M. Paroni12, F. Caprioli2,3

Locally injected mesenchymal stem cells (Alofisel Contact E-Mail Address: Takeda) are now an approved therapy in European Union for treatment of vector containing shRNA for COX-2 (hMSCshCOX-2) to knockdown secretion by different experimental colitis models. Pathogenicity of IL-17-secreting intestinal clones is directly implicated in the epithelial barrier disruption through the modulation of tight junction proteins. Conclusion: Intestinal Th17 cell dysfunction is associated to IFNγ production, which in turn affects intestinal permeability through the disruption of epithelial tight junctions.

Introduction: Excessive production of interleukin-6 is associated with active inflammatory bowel disease (IBD). Blockade of the interleukin-6 receptor (IL6R) with a monoclonal antibody (tocilizumab) is licensed for treatment of rheumatoid arthritis. Clinical trials of IL6R inhibitors in IBD have been small in numbers, with varying efficacy. The IL6R SNP rs2228145 associates with a similar pattern of effects to tocilizumab therapy (higher soluble IL6R, lower c-reactive protein and fibrinogen), making it an attractive genetic instrument for drug target validation.

Aims and Methods: We performed a two sample Mendelian randomization study of IL6R SNPs with impaired IL6R signaling (lower soluble IL6R, lower c-reactive protein and fibrinogen) using genome-wide association study (GWAS) summary statistics.

Results: In a fixed-effects meta-analysis of 26788 cases with Crohn’s disease (CD), 23045 with ulcerative colitis (UC) and 61630 controls, genetically elevated IL6R was associated with decreased odds of Crohn’s disease (CD) odds ratio (OR) 0.87, 95% CI 0.82–0.92, p = 0.000001463 and ulcerative colitis (UC) (OR 0.92, 95% CI 0.89–0.99, p = 0.0378) per 2-fold increment.

Conclusion: On the basis of genetic evidence in human beings, defective IL6R signaling is a strong candidate to protect against the development of both CD and UC; it is an attractive an drug target suitable for further exploration. Genetic studies in populations could be used more widely to help validate and prioritize novel drug targets or to repurpose existing agents for new therapeutic and preventive uses.

OP107 CD103⁺ DENDRITIC CELLS ARE SPECIFICALLY DECREASED IN THE INFAMED COLON FROM PATIENTS WITH ULCERATIVE COLLITIS BUT NOT IN CROHN'S DISEASE

¹Hospital Universitario de La Princesa, IIS-IP and CIBERehd, Madrid, Spain

Contact E-Mail Address: d.bernardoorzid@gmail.com

Introduction: Inflammatory bowel disease (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), is a chronic inflammatory disease of the human gastrointestinal (GI) tract. Dendritic cells (DC), the most potent antigen presenting cells, are essential to maintain the mechanisms of GI-homeostasis towards nutrients and commensal in health, while initiating immune responses towards pro-inflammatory invading pathogens. However, despite the relevance of DC in modulating GI-immune responses, there is not much information about DC composition in the human GI-tract both in health and IBD.

Aims and Methods: Our aim was to characterize human GI-DC subsets, phenotype and function both in health and in IBD patients. To that end, human intestinal biopsies were obtained from healthy controls and IBD patients (including UC and CD, both active and quiescent). Tissue was disaggregated and the lamina propria mononuclear cells (LPMC) characterized by flow cytometry.

Results: Human intestinal DC were identified within singlet viable leukocytes as CD14⁻CD4⁺HLA-DR⁺CD1c⁺. Type 1 conventional DC were defined as CD11c⁺I-κBα⁻CD123⁻, while type 2 conventional DC were identified as SIRPα⁺, while further divided into subsets based on the expression of CD103. Total DC numbers were indeed further divided into subsets based on the expression of CD103 and SIRPα. Type 1 (minority) and type 2 (majority) DC further decreased in the duodenum. Type 1 (minority) and type 2 (majority) (either distal or proximal) compared with the ileum. DC numbers were indeed further divided into subsets based on the expression of CD103. Total DC numbers were indeed further divided into subsets based on the expression of CD103 and SIRPα. Type 1 CD103⁺ DC had higher levels of HLA-DR, CD40, CCRL, CD137, ICOSL and PD-L1. CD103⁺ DC were also more phagocytic and were acquired in multiple integran genes in inflammatory bowel disease. Nut. Genet. 2017; 49(7); 979–986.

Conclusion: Our data indicate that ADR-driven signals inhibit pathogenic responses in the gut of CD patients.

Introduction: In coeliac disease (CD), tolerance to gluten (gliadin) proteins from cereals is lost. Tolerogenic immune modifying nanoparticles (TIP) are effective at restoration of antigen-specific immune tolerance in various autoimmune conditions. The identification of gliadins as dietary antigens and drivers of immune-mediated pathology in CD suggests that TIP containing gliadin (TIP-GLIA) may serve as a cure.

Aims and Methods: Here, we tested immunomodulatory effects of TIP-GLIA vs. control TIP in 3 different mouse models of CD, 1) a delayed-type hypersensitivity, 2) a HLA-DQ2 transgenic, and 3) a gliadin memory T cell enteropathy model. Nanoparticles were administered intravenously.

Results: Treatment with TIP-GLIA reduced gliadin-specific T cell proliferation, inflammatory cytokine secretion, circulating gliadin-specific IgG IgG2, and T cell proliferation. Protective effects were also observed on CD11b⁺/CD11c⁺ DC following mucosal conditioning. The specific reduction of CD103⁺ DC in the inflamed mucosa from UC patients, but not CD, suggests the presence of different pathogenic mechanisms occurring in IBD.

Conclusion: Nothing to disclose

Introduction: Refractory celiac disease type II (RCDII) is an indolent intestinal tumor of aberrant intraepithelial T-lymphocytes (IEL). The severe enteropathy found in RCDII is caused by aberrant IEL that exert cytotoxicity against the enterocytes. In this study, we investigated the cell death mechanisms that are responsible for villous atrophy in RCDII and their potential diagnostic and therapeutic implications.

Aims and Methods: mRNA and protein expression were determined using RT-MLPA analysis, immunofluorescence and flow cytometry, respectively. Enterocyte killing and degranulation by aberrant IEL were measured in the presence of a transwell, specific inhibitors or therapeutic agents, using flow cytometry. Secretion of granzyme B was detected by ELISA.

Results: mRNA and protein expression of granzyme B were significantly upregulated in the cytoplasm of aberrant IEL of patients with RCDII compared to levels of granzyme B expression in patients with celiac disease on a gluten-free diet (GFD). The level of granzyme B expression in RCDII patients correlated with the severity of villous atrophy and with clinical response to therapy. RCDII cell lines also demonstrated increased levels of granzyme B expression. Furthermore, in RCDII patients and RCDII cell lines degranulation and secretion of granzyme B were observed in the presence of epithelial cells. Incubation of RCDII cell lines with epithelial cell line Caco2 showed that aberrant IEL induced apoptosis of Caco2. Treatment with a granzyme B inhibitor demonstrated that killing of enterocytes was granzyme B dependent and that degranulation by IEL was imperative. In addition, we found that the aberrant IEL induced cell death through triggering of the intrinsic apoptosis pathway via mitochondrial membrane depolarization and caspase-3 and -9 activation. For degranulation of granzyme B and killing of the enterocytes, binding of the aberrant IEL to the epithelial cell was necessary. CD103(eGF) expression was significantly increased in RCDII patients compared to CD patients on GFD. Functional studies revealed that CD103(eGF)7-E-cadherin interaction was essential for release of granzyme B and loss of enterocytes. Treatment with therapeutic agent etrolizumab, an anti-P7 mAb, inhibited degranulation of granzyme B and killing of the epithelial cells by RCDII cell lines.

Conclusion: Killing of enterocytes in RCDII is dependent on upregulated expression of granzyme B and interaction with the aberrant IEL through CD103(eGF)7-E-cadherin binding. These data contribute to a better understanding of the pathogenesis of villous atrophy in RCDII and therefore can be important for diagnostic purposes and during follow-up of RCDII patients. Moreover, our preclinical findings support the potential use of etrolizumab as a novel therapeutic agent for the treatment of RCDII patients.

OP112 COELIAC DISEASE DIAGNOSIS IN INDIVIDUALS ON A GLUTEN-FREE DIET

1Hospital Clinico San Carlos de Madrid, Gastroenterology, Madrid, Spain
2Instituto de Investigación Biomédica del Hospital Clinico San Carlos (IdISSC), Madrid, Spain
3Hospital Clinico San Carlos, Madrid, Spain
4Hospital Universitario La Paz, Madrid, Spain
Contact E-Mail Address: laurrederoe@gmail.com

Introduction: Coeliac disease (CD) is a gluten-dependent enteropathy that develops in genetically susceptible individuals. Current treatment is a gluten-free diet (GFD), which leads to the recovery of the normal morphology and function of the intestine, with the subsequent disappearance of clinical symptoms and specific antibodies. Therefore, CD diagnosis needs to be established under gluten containing diet, a problem due to the increasing number of individuals following a GFD.

Aims and Methods: Based on the study of Han et al. (1), we studied the utility of detecting activated γδ and CD8 T cells expressing gut-homing receptors after a 3-day gluten challenge aimed to diagnose CD in individuals on a GFD. We studied 18 patients previously diagnosed with CD and 20 controls, mainly composed by healthy volunteers that followed a gluten containing diet, a problem due to the increasing number of individuals following a GFD for at least 1 month. All subjects were exposed to 12-15 g of gluten every day for 3 consecutive days. Peripheral blood was collected before (day 0) and 6 days after the gluten challenge aimed to diagnose CD in individuals on a GFD.

Results: The 3-day gluten challenge was completed by all participants. In all of them, the studied T cell populations were undetectable or barely present at day 0, but on day 6, γδ and CD8 T cells coexpressing CD103, CD7 and CD8 were observed in every CD patient, but only in 1 control. No differences were observed between patients with high and low/low-HLA risk genetics.

Conclusion: A short gluten challenge elicits the activation of CD103+CD8γδT cells that can be detected by flow cytometry in peripheral blood, even in those patients with a more difficult diagnosis, opening new possibilities for CD diagnosis in individuals on a GFD.

OP113 CLASSIFICATION OF REFRACTORY CELIAC DISEASE WITH FLUORESCENCE-ACTIVATED CELL SORTING OF INTESTINAL LYMPHOCYTES: DATA FROM A TERTIARY REFERRAL CENTER

Charité Universitatsmedizin Berlin, Division of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany

Contact E-Mail Address: federica.branchi@gmail.com

Introduction: Refractory celiac disease (RCD) is classically categorized into two different entities: RCD type I is an autoimmune disease that responds to immunosuppression while in RCD type II a monoclonal transformation of IEL is found. This is usually detected by means of TCR clonality analysis. Patients with RCD type II have a poor prognosis and a high risk of development of enteropathy-associated T-cell lymphoma (EATL), so that it has been proposed to consider RCD type II as a low-grade intraepithelial lymphoma (pre-EATL). Recently, flow cytometric analysis of isolated intestinal lymphocytes has been introduced as new diagnostic modality for the detection of so-called aberrant intestinal lymphocytes (ILs).

Aims and Methods: The purpose of this study was to (i) detect aberrant ILs in a cohort of non-celiac, celiac and RCD patients by means of flow cytometry, (ii) to verify whether there is an association between cellular characteristics of RCD patients and presence of aberrant ILs, (iii) to evaluate the diagnostic accuracy of aberrant ILs for RCD pre-EATL in our cohort.

Immunostaining (CD3, CD4, CD8, CD7, CD103, TCRγδ, lineage markers) and flow cytometric analysis of isolated IELs from duodenal biopsies of patients with RCD, uncomplicated CD and controls were performed. Aberrant ILs were defined by means of different gating strategies including cytCD3+/surfCD3−/CD7−/CD103− (Table 1). Patients with evidence of aberrant ILs also showed significantly more criteria for severe malabsorption (as assessed by a cumulative malabsorption score). A cut-off of 11% ILs for the most reliable strategy allowed to identify a subgroup of low risk RCD patients (n = 21) and a small group of high-risk RCDs (n = 5) that were classified as pre-EATL (2 of them with a later EATL diagnosis). Nevertheless, sensitivity gaps were uncovered: 1 patient with ulcerative jejunoileitis who later developed an EATL was not identified as pre-EATL. Furthermore, 2 overt EATL cases were false negative (i.e., overall sensitivity 67%, NPV 89%). Alternative, simpler gating strategies for aberrant ILs showed similar accuracy to the main strategy.

Conclusion: In clinical practice, flow cytometry of aberrant ILs may be a simple predictor of high-risk RCD. However, its use as the only diagnostic strategy for classifying patients in RCD I (low risk) and RCD II pre-EATL may also lead to misclassification. A multimodal diagnostic approach for the diagnosis of RCD (including TCR clonality and malabsorption score) maximizes diagnostic accuracy.

References
It is necessary to externally validate the score and conclusion:

49.3%

High-risk group (≥21 points): 21.2%

Medium-risk group (17-24 points): 4.4%

Low-risk group (<17 points): 95.8%

Hospitalization for less than 30 days (100% versus 68.4%, p = 0.0002). The prevalence of Diabetes Mellitus (71.7% versus 31.6%) and hepatocellular carcinoma (33.6% versus 31.6%) were not relevant as factors predisposing to MDRO infection (p = 0.6526 and p = 0.9214, respectively).

Conclusion: Indiscriminate use of antibiotics and PPIs increases the risk of MDRO infections, suggesting that the prescription of these drugs should be restricted to formal indication. Also hospitalization for more than 48 hours or hospital discharge for less than 30 days have been shown to influence the onset of MDROs. This suggests that hospitalizations in LC patients should be limited to the minimum number of days and risk factors should be identified to prevent the emergence of these microorganisms.

Introduction: Infections in patients with liver cirrhosis (LC) are common and one of the major causes of hospitalization. Multidrug-resistant organisms (MDROs) are a current reality that can alter the paradigm of treatment and prevention of infection in these patients.

Aims and Methods: The aim of this study is to identify the risk factors for the occurrence of MDROs in patients with LC. Prospective study from October 2017 to March 2018 in consecutively hospitalized patients with uncomplicated LC with infection. Blood, urine and ascitic fluid cultures were analyzed.

Results: 52 episodes of infection (43 males, mean age 63 ± 14.6 years, 30 Child-Pugh B or C, 15 episodes no microorganisms were identified) were analyzed in the last 90 days (including norfloxacin prophylaxis) (94.4% versus 47.4%, p = 0.0033) and hospitalization for more than 48 hours or discharge for less than 30 days (100% versus 68.4%, p = 0.0082). The presence of Diabetes Mellitus (71.7% versus 31.6%) and hepatocellular carcinoma (33.6% versus 31.6%) were not relevant as factors predisposing to MDRO infection (p = 0.6526 and p = 0.9214, respectively).

Conclusion: Indiscriminate use of antibiotics and PPIs increases the risk of MDRO infections, suggesting that the prescription of these drugs should be restricted to formal indication. Also hospitalization for more than 48 hours or hospital discharge for less than 30 days have been shown to influence the onset of MDROs. This suggests that hospitalizations in LC patients should be limited to the minimum number of days and risk factors should be identified to prevent the emergence of these microorganisms.

Introduction: Muscle cramps are common in patients with liver cirrhosis and adversely influence quality of life with no available highly effective treatment.

Aims and Methods: The aim of this study was to assess the efficacy and safety of orphenadrine in treatment of muscle cramps in cirrhotic patients. Methods: 122 patients with liver cirrhosis were enrolled in this study who suffering from frequent muscle cramps (≥ 3 per week), randomized to receive either orphenadrine 100 mg twice daily or placebo for 1 month twice daily as a control.
33 patients in the orphenadrine group and 36 patients in the placebo group were on diuretic treatment. Orphenadrine was administered orally in a single dose of 15 mg every 4 hours. The overall compliance with the medication was found to be high, with over 80% of patients taking the medication as prescribed.

Results: The results of the study showed a significant difference in the incidence of muscle cramps between the orphenadrine and placebo groups. The incidence of muscle cramps in the orphenadrine group was 14% vs. 28% (p < 0.001). The side effects were few such as dry mouth, drowsiness, and nausea, with no significant difference between their occurrences in the 2 groups.

Conclusion: Orphenadrine is safe and effective in treatment of muscle cramps in patients with liver cirrhosis.

Disclosure: Nothing to disclose.

OP118 EFFECTIVENESS OF ACTIVE OUTPATIENT FOLLOW-UP PROGRAM ON LONG-TERM SURVIVAL OF PATIENTS WITH ALCOHOLIC LIVER DISEASE

V. Lunkov1, M. Maevskaya1, V. Ivashkin1
1Federal State Autonomous Educational Institution of Higher Education I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation (Sechenov University), Hepatology Department, Moscow, Russian Federation

Contact E-Mail Address: vdunkov@gmail.com

Introduction: Alcoholic liver disease (ALD) is the most prevalent cause of advanced liver disease and liver-related mortality in Europe and Russia. Abstinence is the first line and the basic therapeutic procedure for any form and stage of ALD. Combined comprehensive supportive and behavioral (repeated short brief intervention sessions) treatments provided by clinicians may increase abstinence rate followed by liver function stabilization and improves patient’s outcome.

Aims and Methods: The main aim of this study was to estimate the effectiveness of the active outpatient follow-up (AOF) program in achieving and maintaining abstinence, liver function compensation and improving the long-term outcome of patients with ALD.

In this historical control study 29 patients with ALD were enrolled in the group of AOF that included active supervision by hepatologist: physical and motivation assessment, motivational interviewing, liver panel lab tests with the rate once at 3 months. The duration of the AOF was 12 months with 1 follow-up visit after 12 month. The historical control group included 36 patients with ALD and history of 2-year follow-up in the hepatology department, who received comprehensive therapy and education to avoid alcohol.

Results: There were significant differences in adherence to abstinence between AOF and control groups at 6 (88% vs 43%, p < 0.001), 9 (84% vs 44%, p < 0.001), 12 (81% vs 44%, p < 0.001) and 24 (80% vs 40%, p = 0.007) months of follow-up, respectively. The 24-month alcohol relapse occurred in 2 (8%) patients in the AOF group compared with 13 (36%) patients in the control group (p = 0.005). Unvariable analysis showed that only AOF was significantly associated with abstinence and maintaining of abstinence. Multivariable regression analysis of alcohol relapse during the 24 month showed that AOF is independent factor for being abstenor (OR: 0.80 [95% CI 0.14-0.479]; p = 0.006).

Conclusion: The program of active outpatient follow-up provided by hepatologist can increase likelihood of achieving and maintaining abstinence, prolonged compensation of liver function and improve the long-term survival of patients with ALD.

Diagnosis and risk factors of pancreatic diseases – Room L8

OP120 DEFINING PANCREATITIS AS A RISK FACTOR FOR pancreatic cancer: THE ROLE, INCIDENCE, AND TIMELINE OF DEVELOPMENT

A. Syed1, S. Thakkar2
1Allegheny Health Network, Gastroenterology, Pittsburgh, United States
2Allegheny Health Network, Gastroenterology, Sewickley, United States

Contact E-Mail Address: shyamtdoc@gmail.com

Introduction: Pancreatic cancer has a high mortality rate and is the third leading cause of cancer related deaths in the United States. Risk factors for developing pancreatic cancer include age > 55, male sex, obesity, tobacco, and diagnosis of diabetes. Additionally, acute and/or chronic pancreatitis has been implicated as an important risk factor for pancreatic cancer; however, the incidence and temporal relationship of pancreatitis prior to the diagnosis of pancreatic cancer is unclear.

Aims and Methods: We aim to establish the role and incidence of pancreatitis temporally with the development of pancreatic cancer. A population-based study, with a web-based platform called Explorys was used to collect de-identified patient data. Over 50 million patients, spanning nationally in over 20 health-care systems’ electronic medical records is in this cloud-based, HIPPA-enabled platform. Data was obtained using ICD-9 code criteria with search terms “acute pancreatitis,” “chronic pancreatitis,” and “malignant tumor of the pancreas.” A temporal relationship between pancreatitis diagnoses, followed by pancreatic cancer diagnosis was investigated. Intervals of 3, 6, 12, 24, and 36 months were observed. Demographic data, including age, gender, and race was also recorded and analyzed.

Results: A total 50,080 patients were found to have a diagnosis of pancreatic cancer. 7,420 (14.8%) of these patients were found to have diagnoses of pancreatitis prior to their cancer diagnoses. Of those, 91.6% were between the ages of 45-89. Interestingly, there was a higher incidence of pancreatic cancer in the African-American population vs. the Caucasian population (21.2% vs 14.8%, p < 0.05) group with prior pancreatitis diagnosis. Further analysis of pancreatic cancer diagnosis revealed that 6,030 of the 7,420 patients were diagnosed within 3 months of their acute and/or chronic pancreatitis (81.3%) diagnosis. Finally,

Introduction: The documented incidence of pediatric pancreatitis (PP) is low, but it shows a rising pattern from Eastern to Western Europe and the USA. The cause of this phenomenon is not clear, but based on a single center study the amylase and lipase measurements correlate with the incidence of the disease.

Aims and Methods: The aim of the PINEAPPLE study is to investigate the current diagnostic practice for PP and to estimate the occurrence of pancreatitis among children suffering from abdominal pain. Furthermore we would like to develop an IBM guideline to establish a scoring system in order to evaluate the necessity of diagnostic steps for PP in children with abdominal pain. PINEAPPLE is a registered (ISRCTN53618458), observational, multinational clinical trial and the pre-study protocol is published (http://www.dnm.nlm.nih.gov/pubmed/26641250).

Results: PINEAPPLE-R: 9.7% (2775/28707) of the children appeared at ER unit with abdominal pain. In case of abdominal pain sPEM was performed in 14% whereas 32% of the patients had transabdominal ultrasonography. In our cohort the number of sPEM decreases from the USA (21.6%) to Eastern Europe (13% in Hungary and 0.6% in Romania) and it correlates (r = 0.97) with the incidence of PP (0.775). PINEAPPLE-P: 8 pancreatitis from 496 patients with abdominal pain were diagnosed. Positive family history and upper abdominal pain were characteristic for PP but fever and forced posture were not typical.

Conclusion: The PINEAPPLE-R shows that the incidence of PP is 0.3% among children with abdominal pain based on the current diagnostic practice. Better awareness of PP results 1.6% incidence of PP as a reason of abdominal pain. These data strongly suggest that acute pancreatitis is underdiagnosed in children.

Disclosure: Nothing to disclose.

OPI123  IS DIABETES BEING IGNORED IN PATIENTS WITH PANCREATIC CANCER?

A. Syed1, S. Thakkar2

1Allegheny Health Network, Gastroenterology, Pittsburgh, United States
2Allegheny Health Network, Gastroenterology, Sewickley, United States

Contact E-Mail Address: shyamtdoc@gmail.com

Introduction: Many risk factors have been implicated in pancreatic cancer, including age > 55, male gender, obesity, tobacco use, pancreatitis and diabetes mellitus (DM). It has been reported in literature that as high as 80% of patients with pancreatic cancer have glucose intolerance or frank diabetes.

Aims and Methods: We aim to evaluate if physicians are diagnosing, reporting, and managing diabetes in patients with pancreatic cancer. A population-based study, using an IBM platform called Explorys, was used to collect de-identified patient data. Over 50 million patients, spanning nationally in over 40 healthcare systems’ electronic medical records (EMR) is in this cloud-based, HIPPA-enabled platform. Data was obtained using ICD-9 code criteria with search terms “diabetes mellitus” and “malignant tumor of the pancreas.” Further, patients were also included if they were on anti-diabetic medications, including metformin, sulfonylureas, and insulin. These search terms were observed to ensure diagnosis of DM after pancreatic cancer as a first occurrence. Subsequently, HbA1c levels were observed in correlation to rates of mortality within this cohort.

Results: A total of 50,080 patients in the Explorys database with diagnosis of pancreatic cancer. Of those, 20,160 (40.3%) had concomitant diagnosis of DM in their EMR. African-Americans had a higher rate of DM development when compared to Caucasians (50.2% vs. 39.9%, p < 0.001). Majority of the diabetic patients were aged 60-89, with predominance between 70-79. As levels of HbA1c increased, rates of mortality did as well. Patients with HbA1c levels between 4-6.4% were found to have a lower mortality rate than those with HbA1c levels in the range between 6.5-8% (44.8% vs. 46.6%, p=0.0293) and 9-12% (44.8% vs. 47.6%, p=0.00672).

Conclusion: It has been reported in literature that as high as 80% of patients with pancreatic cancer have concomitant diagnoses of DM. We found drastically different percentages; these variations may be due to several factors. Firstly, it is very possible clinicians are underdiagnosing diabetes, especially in patients with pancreatic cancer. It is possible because of the high mortality of these patients, their other diagnoses, including DM, are being overlooked. Secondly, if DM is being diagnosed, physicians are not adequately reporting it in a patient’s EMR. Moreover, patients with DM with HbA1c levels greater than 6.5% have a higher rate of mortality as compared to patients with HbA1c levels below 6.5%. Clinicians need to be aware of the high incidence of DM in patients with pancreatic cancer, so proper diagnosis and management can be implemented to possibly decrease mortality. Increased awareness should be also be in elderly patients between 60-69, as well as the African-American population where prevalence was highest.

Introduction: Locally advanced pancreatic cancer (LAPC) is associated with a poor prognosis. Current standard treatment is limited to chemotherapy or chemo-radiotherapy. Novel treatment approaches are crucial in attempting to combat this unmet medical need. Phosphorus-32 (P-32) Microparticles is a brachytherapy device that implants a predetermined dose of the beta radiation emitting isotope (P-32) directly into pancreatic tumours via endoscopic ultrasound (EUS) guidance. The presented data are early results from an ongoing international, multi-institutional, single-arm pilot study. The study objective is to determine the safety and efficacy of P-32 Microparticles in a patient population undergoing standard chemotherapy for unresectable LAPC.

Aims and Methods: Eligible patients were allocated to receive either gemcitabine+na-paclitaxel or FOLFIRINOX by physician choice. P-32 implantation took place during the 4th or 5th week following the initiation of chemotherapy. P-32 was implanted directly into the pancreatic tumour via EUS guidance, using a fine needle aspiration (FNA) needle. Each patient’s dose was calculated from the tumour volume where the absorbed dose of P-32 to the tumour was calculated to equal 100 Gy. Diffusion pattern of the P-32-suspension following implantation was assessed by EUS and by Bremsstrahlung SPECT/CT imaging. Chemotherapy was continued after the implantation. Safety data was collected weekly and toxicity was graded using the Common Terminology Criteria for Adverse Events (CTCAE). Cetuximab read CT scans were conducted every 8 weeks to assess response defined as complete response (CR), partial response (PR), and stable disease (SD) rate, according to RECIST 1.1 criteria. FDG-PET scans were performed at baseline and at week 12.

Results: Data is reported on the first 20 implanted patients (12 males and 8 females, median age 65 years [range 54-84]) up to week 16 of follow-up. At 16 weeks, the objective response rate was 20% – PR in 4/20 patients. The local disease control rate (CR, PR and SD) was 85% – either PR or SD in 17/20 patients. Median change in tumour volume from baseline to week 16 was 33% (range +56% to -80%). Total lesion glycolysis (TLG) as measured via FDG-PET scan showed a median reduction of 54% (range +45% to -100%) from baseline to week 12.

The EUS-guided implantation was carried out successfully in all patients and with no serious complications. By week 16, 318 adverse events (AEs) were reported. 33 Grade 3 AEs (10%) and 6 (2%) Grade 4 toxicities were reported. The most common AEs of Grade 3 and 4 severity were neutropenia (7), anaemia (2), constipation (2), vomiting (2) and fatigue (2). None of the G3 and G4 AEs were attributable to the device or the implantation procedure.

Conclusion: Early data indicates that the use of EUS-guided implantation of P-32 is highly feasible, well tolerated and has an acceptable safety profile in combination with standard first-line chemotherapy for LAPC. Preliminary data shows evidence of tumour regression and local disease control. These results, however, warrant further evaluation. The clinical trial is ongoing and additional safety and efficacy data will be presented.

Introduction: An antiflux metal stent (ARMS) for nonresectable malignant biliary obstruction may prevent recurrent biliary obstruction (RBO) caused by common bile duct (CBD) or distal common bile duct (DCBD) stricture. The superiority of the ARMS over conventional covered self-expandable metal stents (SEMSs) has not fully examined.

Aims and Methods: We conducted a multicenter randomized controlled trial to examine whether RBO of an ARMS with a funnel-shaped valve was longer than that of a covered SEMS in patients without a history of SEMS placement. Secondary outcomes included causes of RBO, adverse events, and patient survival.

Results: We enrolled 104 patients (52 patients per arm) from September 2014 to June 2016 at 11 tertiary care centers in Japan. The median TRBO did not differ significantly between the ARMS and covered SEMS groups (251 days vs 351 days, respectively; p = 0.11). RBO due to biliary sludge or food impaction was observed in 13% and 9.8% patients who received an ARMS and covered SEMS, respectively (p = 0.038). The ARMS appeared to be associated with a higher rate of stent migration compared with the covered SEMS (31% vs 12%, respectively; p = 0.038). No significant between-group difference was observed for adverse events or patient survival.

Conclusion: The current ARMS is neither associated with longer TRBO compared with the covered SEMS. Further modifications including addition of an anti-migration system are required to justify the use of the current ARMS as a first-line palliative treatment modality for distal malignant biliary obstruction.

Disclosure: The authors declare no conflicts of interest.

OP127 EUS-GUIDED BILARY DRAINAGE VERSUS ERCP FOR THE PRIMARY PALLIATION OF MALIGNANT BILIARY OBSTRUCTION: A MULTICENTER RANDOMIZED CLINICAL TRIAL

Contact E-Mail Address: dhpark@amc.seoul.kr

Introduction: Although ERCP for the palliation of malignant biliary obstruction is the standard care, post-procedure pancreatitis and stent dysfunctions are not uncommon. While endoscopic ultrasound (EUS)-guided biliary drainage (EUS-BD) is garnering interest as a viable option when ERCP is impossible, its role as a primary palliation of malignant distal biliary obstruction is yet to be proven.

Aims and Methods: The aim of the study was to determine whether EUS-BD is comparable to conventional transpapillary stenting with ERCP in the primary palliation of malignant distal biliary obstruction. We performed a randomized allocation to EUS-BD or ERCP in 125 patients with unresectable malignant distal biliary obstruction at four tertiary academic referral centers in South Korea.

Results: Technical success rates were 93.8% (60/64) for EUS-BD and 90.2% (55/61) for ERCP (difference 3.6%, 95% 1-sided confidence interval lower limit 0.44%, p = 0.003 for noninferiority margin of 10%). Clinical success rates were 90.0% (54/60) in EUS-BD and 94.5% (52/55) in ERCP (p = 0.49). Lower rates of overall adverse events (6.3% vs 19.7%, p = 0.03) without post-procedure pancreatitis (0.0% vs 14.8%), reinfection (15.6% vs 42.6%), and higher rate of stent patency (85.1% vs 48.9%) were observed with EUS-BD at the study end. EUS-BD was associated with more preserved QoL than transpapillary stenting after 12 weeks of the procedure.
Conclusion: This study demonstrated comparable technical and clinical success rates for ERCP in relief malignant distal biliary obstruction. Coupled with longer duration of bile duct patency, lower rates of adverse events and re-intervention, EUS-BD should be considered as a viable primary treatment option in patients with distal biliary obstruction from unresectable malignancy.

2University of Milan, Gastroenterology and Endoscopy Unit, Milano, Italy

Introduction: Excessive excitation of the esophageal smooth muscle is thought to induce esophageal hypercontractility. Abnormal inhibition can lead to prematurity esophageal contractions, with or without abnormal lower esophageal sphincter (LES) relaxation. Esophageal provocative testing (multiple rapid swallows, MRS) during HRM evaluates esophageal excitation and deglutitive inhibition, and could provide insights into the pathophysiology of hypercontractile esophageal disorders.

Aims and Methods: We aimed to evaluate interrelationships between excessive excitation and abnormal inhibition in esophageal hypercontractile disorders, using MRS. Esophageal HRM fulfilling Chicago Classification 3.0 criteria for hypercontractile esophagus (HE) with and without esophageagastic junction (EGJ) obstruction were reviewed from 5 centers (4 in Europe, 1 in US). Incomplete studies, and prior foregut surgery were exclusions. Upper endoscopy and barium studies excluded structural processes (rings, hiatus hernia, stricture). Single swallows (SS) and MRS were analyzed using HRM software tools assessing integrated relaxation pressure (IRP, >15 mmHg·cm·s) excitation, distal latency (DL) and distal contractile integral (DCI); MRS:SS DCI ratio >1 defined contraction reserve. Comparison groups were achalasia type 3 (positive control for EGJ obstruction) and healthy volunteers (negative control).

Results: Study groups consisted of 40 patients with HE (62.6 ± 2.0, 63% F), 30 with HE and EGJ obstruction (65.6 ± 2.7, 55% F), 72 with achalasia type 3 (66.2 ± 2.0, 30% F) and 18 normal controls (27.4 ± 6.7, 56% F). Higher mean DCI values were noted in HE and HE with EGJ obstruction groups (p = ns between SS and MRS, and between groups), these DCI values were significantly higher than comparison groups (p < 0.0001 for each comparison). MRS:SS DCI ratio was lower in HE with obstruction compared to achalasia type 3 (p = 0.03) and normal controls (p < 0.001), and trended toward significance in HE vs. achalasia type 3 (p = 0.16). Proportions with contraction reserve were lower in HE subgroups (p = 0.03 across groups). Incomplete inhibition was similar between EGJ obstruction categories (HE: with obstruction, achalasia type 3, p = ns), and lower in HE without obstruction (p = 0.04 vs. achalasia type 3, p = 0.06 vs all obstructive categories). On symptom analysis, perceptual symptoms (heaviness, chest pain) were common in HE subgroups (p = 0.09 across groups), while transit symptoms (dysphagia) were more frequent in the setting of EGJ obstruction.

Conclusion: The esophageal smooth muscle demonstrates excessive excitation at HE subgroups, manifest as high DCI and diminished contraction reserve on MRS. In contrast, abnormal inhibition is predominant in achalasia type 3, and participates in the pathophysiology of HE with obstruction. Our findings indicate that the balance of excitation and inhibition defines the clinical and therapeutic manifestations of HE, HE with obstruction and achalasia.

Disclosure: Nothing to disclose.

Introduction: Cough reflex sensitivity to inhaled irritants is influenced by the functional state of cough-triggering afferent nerve terminals in the larynx and large airways. Laryngopharyngeal reflux (LPR) causes irritation of the larynx and possibly large airways. However, the relationship between the cough reflex sensitivity to inhaled irritants and LPR is incompletely understood.

Aims and Methods: We hypothesized that cough reflex sensitivity in patients with LPR is positively correlated with LPR. Our hypothesis predicts that patients with more frequent LPR have lower cough reflex threshold. Consecutive patients referred for LPR were evaluated and those with positive reflux symptom index (RSI > 13) and/or reflux finding score (RFS > 7) were evaluated. LPR was evaluated by 24-hour dual pharyngeal and distal esophageal 24-hour pH/impedance monitoring. Appropriate distance between pharyngeal and distal esophageal pH sensors was chosen based on manometrically determined LES and UES. LPR event was inferred from the pharyngeal reflux following reflux detection in the distal esophagus. For each LPR event we determined the maximum drop of pH at the pH levels < 6, < 5.5, > 5.0, < 4.5 and < 4.0 to perform the analysis independently of the assumption how the pH of LPR is required to affect the LPR episodes with pH drop.

Correlations between cough reflex sensitivity expressed as C5 and the numbers of LPR episodes, irrespective of the acidity of the LPR event. Cough reflex sensitivity was determined by single breath capsaicin inhalation challenge of doubling concentrations of capsaicin (0.01–0.1 mg/ml). Seven subjects who demonstrated the lowest concentration of capsaicin that evoked at least 2 coughs (C2) or 5 coughs (C5). Statistical analysis C2 and C5 values were log transformed and Pearson coefficients were calculated for correlation with reflux parameters.

Results: 27 consecutive patients were evaluated. The number of LPR events that reached pH 6.0, 5.5, 5.0, 4.5 and 4.0 was 14[8-21], 42[7], [0-2], [0-1], [0-0]. Correlations between cough reflex sensitivity expressed as C5 and the numbers of LPR episodes with pH drop to < 6.0, 5.5, 5.0, 4.5 and 4.0 as expressed as the R value were 0.07, 0.04, 0.01, 0.02, 0.23, respectively (p > 0.1 not significant in all cases). Correlations between cough reflex sensitivity expressed as C2 and the number of LPR episodes, irrespective of the acidity of the LPR event.

Conclusion: The number of LPR episodes does not correlate with the cough reflex sensitivity in patients with laryngopharyngeal reflux, irrespective of the acidity of LPR event. This suggests that a direct simple relationship between the intensity of laryngeal irritation and cough is improbable.

Introduction: Anti-Reflex Endoscopic Surgery (ARES) is a new efficacious treatment of option for gastroesophageal reflux disease (GERD). We propose to define “esophageal remodeling” as the functional restoration of the esophagogastric junction (EGJ) that involves increased lower esophageal sphincter (LES) pressure. ARES is a esophageal fundoplication technique using endoscopic mucosal resection (EMR) to treat such refractory GERD patients. This study investigated the clinical outcomes of ARES for refractory GERD patients.

Aims and Methods: ARES was performed in 106 patients with drug-refractory GERD from December 2015 to July 2017. We analyzed data from a prospectively collected database of ARES subjects, which included preprocedure and 6-month postprocedure of GERD-Q symptom scores, and results from esophageal high resolution manometry (HRM) and 24-hour pH monitoring. Symptom control rates were compared according to clinical and surgical factors to identify predictive factors of successful surgical outcomes.

Results: ARES was performed for 106 patients (55% male; mean age 46.8 years) with PPI-refractory GERD. Mean PPI medication periods were 5.7 (1-30) years and ARES procedure time was 32.6 (15.8-33) minutes. The GERD-Q score and 24hr pH monitoring were significantly improved after ARES. Mean post-treatment GERD-Q score was 7.54 ± 2.6, compared to 10.87 ± 2.7 pre-treatment (p < 0.001). In impedance planimetry, the mean distensibility was 16.1 ± 8.3 prior to treatment and 19.7 ± 10.2 significantly complications after ARES were occurred. But 6 patients underwent post-treatment stricture, and were treated using balloon dilution and steroid injection. 3 patients suffered from minor post-ARES bleeding, successfully treated with argon plasma coagulation.

Conclusion: ARES is a very effective and safe treatment option for PPI-refractory GERD patients. ARES can be a good alternative treatment for refractory GERD.

Support: Nothing to disclose.

Efficacy of RPC4046, an Anti-Interleukin-13 Monoclonal Antibody, in Patients with Active Eosinophilic Esophagitis: Analysis of the Steroid-Refractory Subgroup from the Heroes Study

Introduction: The HEROES study was a 16-week double-blind, placebo-controlled phase 2 multicenter trial that evaluated the efficacy and safety of RPC4046 in adult patients with active eosinophilic esophagitis (EoE). The study included steroid-refractory EoE patients based on post corticosteroid use and investigator judgment. Both pre-specified and post-hoc analyses were undertaken to assess the effect of RPC4046 treatment on this important subgroup.

Aims and Methods: In this study, 99 adult patients with active EoE were stratified by steroid-refractory status (yes/no) and randomized 1:1:1 to receive RPC4046 360 mg, 180 mg, or placebo weekly for 16 weeks. The primary endpoint was change from baseline in mean eosinophil esophageal count at week 16. Secondary endpoints included mean change from baseline to week 16 in EoE Endoscopic Reference Score (EREFS), improvements in dysphagia determined by the Daily Symptom Diary (DSD), Eosinophilic Esophagitis Activity Index (EoEAI) score, and EoE histology scoring system (EoEHSS) based on grade and stage.

Results: Of the steroid-refractory patients, 17 were randomized to RPC4046 360 mg, 14 to RPC4046 180 mg, and 16 to placebo. The differences in change in mean eosinophil eosophageal counts from baseline to week 16 between RPC4046 360 mg and placebo as well as RPC4046 180 mg and placebo were statistically significant. The difference in mean change in EREFS between each RPC4046 group and the placebo group was statistically significant for total score over all esophageal locations. The mean change in DSD composite score in the RPC4046 360 mg group compared to the placebo group approached statistical significance. Statistically significant improvement from baseline to week 16 in the RPC4046 treatment groups also were observed on histology as determined by EoEHSS and on symptom severity as determined by EoEAI. The most frequently reported adverse events in the study were headache, upper respiratory tract infection, arthralgia, nasopharyngitis, and diarrhea.

Conclusion: RPC4046 treatment improved mean and peak eosinophil count and histopathologic parameters, improved endoscopic features, and improved symptoms in steroid-refractory EoE patients. Although this pre-specified analysis was undertaken in a subgroup of patients in the HEROES trial, these data provide support that treatment with RPC4046 results in marked improvement in multiple EoE-related disease measures in steroid-refractory EoE patients. In the overall study population, oxolarizim was generally safe and well-tolerated.

EPI13 FIRST-LINE THERAPEUTIC OPTIONS AND EFFECTIVENESS RATES IN EUROPEN PATIENTS WITH EOSINOPHILIC ESOPHAGITIS: INITIAL RESULTS FROM THE EOE CONNECT REGISTRY

Introduction: Eosinophilic esophagitis (EoE) is a chronic immune-mediated inflammatory esophageal disorder characterized by symptoms of esophageal dysfunction and dense eosinophil-predominant infiltration. EoE constitutes a distinct non-IgE mediated food allergy, avoiding specific food antigen is the only therapy that targets the cause of the disease. Limitations from dietary therapy hampering its implementation in clinical practice promoted the use of anti-inflammatory drugs, mainly swallowed topical steroids and proton-pump inhibitor therapy, hampering its implementation in clinical practice.

Results: A total of 407 consecutive patients with LGB were identified 106 of whom (26%) were transfused. We included 115 transfusion episodes in 74 patients (18.2%) with a total of 206 RBC units transfused. Median age was 82.6 years; 59 (79.4%) of patients were over 70, and 54.1% were men. 75 transfusion episodes (65.2%) were appropriate. Over-transfusion occurred in 34 episodes (29.6%). A "1-in-1 transfusion" was performed in only 25 (21.7%) transfusion episodes. The number of over-transfused RBC units was 69 (33.5%).

Conclusion: RBCT in LGB is inadequate in a third of the cases due to over-transfusion, caused by an inappropriate assessment of the relevant Hb threshold in stable patients, and one of Hb thresholds in intensive care patients. The decision-determining factors. Frequency tables were generated for each treatment option. Comparative studies among available options are lacking. The EoE CONNECT registry resulted from the UEG Link Award program is a suitable way to document and understand how the treatment of EoE patients to reduce variability in clinical management.

Introduction: Unnecessary blood cell transfusion (RBCT) increases the risk of side effects and the cost of the treatment of gastrointestinal bleeding, without providing benefits.

Aims and Methods: We aimed to assess the appropriateness of RBCT in acute lower gastrointestinal bleeding (LGB).

Results: A total of 407 consecutive patients with LGB were identified 106 of whom (26%) were transfused. We included 115 transfusion episodes in 74 patients (18.2%) with a total of 206 RBC units transfused. Median age was 82.6 years; 59 (79.4%) of patients were over 70, and 54.1% were men. 75 transfusion episodes (65.2%) were appropriate. Over-transfusion occurred in 34 episodes (29.6%). A "1-in-1 transfusion" was performed in only 25 (21.7%) transfusion episodes. The number of over-transfused RBC units was 69 (33.5%).

Conclusion: RBCT in LGB is inadequate in a third of the cases due to over-transfusion, caused by an inappropriate assessment of the relevant Hb threshold in stable patients, and one of Hb thresholds in intensive care patients. More measures should be implemented to increase the appropriateness of RBCT.

OP136 CAN PROPHYLACTIC ARSENAL PLASMA COAGULATION REDUCE DELAYED POST-PAPILLECTOMY BLEEDING? A PROSPECTIVE RANDOMIZED MULTICENTER TRIAL

1Soonchunhyang University College of Medicine, Cheonan Hospital, Division of Gastroenterology & Hepatology, Department of Internal Medicine, Cheonan, Korea (Republic of) 2Korea University College Of Medicine, Ansan Hospital, Ansan, Korea (Republic of) 3SoonChunHyang University School of Medicine, Digestive Disease Center and Research Institute, Department of Internal Medicine, Bucheon, Korea (Republic of) 4Dankook University Hospital, Dept. of Internal Medicine, Cheonan, Korea (Republic of) 5Inha University Hospital, Dept. of Internal Medicine, Incheon, Korea (Republic of) 6CHU University Bundang Medical Center Digestive Disease Center, Seongnam, Korea (Republic of)

Contact E-Mail Address: thlee@schmc.ac.kr

Introduction: Endoscopic post-papillectomy bleeding usually occurs in 3 to 20% of cases or higher prevalence. Moreover, delayed post-papillectomy bleeding within 1 week is also problematic. However, there is no definite guideline or consensus for prevention or reduction of delayed post-papillectomy bleeding. Additive role of prophylactic argon plasma coagulation (APC) after papillectomy was not defined.

Aims and Methods: The aim of this study was to evaluate the efficacy of prophylactic APC to minimize delayed post-papillectomy bleeding and reduce the recurrence or persistence of residual tumors. A prospective randomized study was performed at 6 tertiary referral centers. Patients with ampulla of Vater adenoma were enrolled and followed from January 2016 to March 2018, and were randomized to either the prophylactic APC or non-APC group. Endoscopic papillectomy was performed using a conventional snaring papillectomy method without submucosal injection. Then, the prophylactic APC group underwent APC on the resection margin. Immediate post-papillectomy bleeding and followed up with duodenoscopy at 1, 6, and 12 months. The main outcome measurements were delayed (> 24 h) post-papillectomy bleeding rate and tumor persistent rate between 2 groups.

Results: In total, 48 patients underwent endoscopic papillectomy. Delayed bleeding rates in the prophylactic APC and non-APC groups were 33.5% (8/24) and 16.7% (4/24), respectively (p = 0.336). Tumor persistence at 1 month did not differ between the 2 groups (8.3% vs. 4.2%, p = 0.401). However, both groups did not have tumor recurrence at 6 months (0/24 and 0/24). The mean tumor length and width were 11 and 12 mm in the prophylactic APC group, and 13.6 and 12.7 mm in the non-APC group. En bloc resection rates in the prophylactic APC and non-APC groups were 83.3% (20/24) and 95.8% (23/24), respectively. Positive resection margin rates in the prophylactic APC and non-APC groups were 66.7% (16/24) and 33.3% (8/24), respectively (p = 0.076). Post-procedure pancreatitis rates were 20.7% (5/24) in the prophylactic APC and 37.5% (9/24) in the non-APC groups, respectively (p = 0.255). The severity of pancreatitis did not differ between the 2 groups. There were no procedure-related mortalities or serious complications.

OP135 RISK OF POST-POLYPECTOMY BLEEDING WITH UNINTERRUPTED CLOPIDOGREL THERAPY: AN INDUSTRY-INDEPENDENT, DOUBLE-BLIND, RANDOMIZED TRIAL

F.-K. L. Chan1, M.H. Kyaw1, J.C. Hsuns1, B.Y. Suens1, K.M. Keen1, Y.K. Tse1, J. Chung1, P. Cheong2, D. Ng2, K.L.Y. Lam1, S.C. Nga1

Contact E-Mail Address: fkchan@cuhk.edu.hk

Introduction: Current guidelines recommend clopidogrel to be interrupted for at least 5 to 7 days before polypectomy. We investigate whether uninterrupted clopidogrel therapy will increase the risk of post-polypectomy bleeding.

Aims and Methods: In this double-blind randomized trial, we screened for patients receiving clopidogrel due to cardiovascular disease who required polypectomy. Patients were instructed to stop taking their prescriptions of clopidogrel 7 days before colonoscopy and were randomized to 7 days of clopidogrel (75mg daily) or uninterrupted clopidogrel group. Primary endpoint was delayed post-polypectomy bleeding defined as rectal bleeding starting after the colonoscope has been retracted from the anus to 30 days after the procedure, with hypotension, a decrease in hemoglobin of > 2 g/dL from baseline, requirement of transfusion, prolonged hospitalization, hospitalization, and or hemostatic intervention. Secondary endpoints were immediate post-polypectomy bleeding and serious cardiothrombotic events. Immediate post-polypectomy bleeding was defined as bleeding at the time of polypectomy that persisted despite continuous irrigation with diluted epinephrine solution for 5 minutes. Serious cardiothrombotic events were defined as non-fatal myocardial infarction, non-fatal stroke, or death from a vascular cause within 6 months of colonoscopy.

Results: A total of 387 patients received colonoscopy of whom 216 required polypectomy. 106 patients in interrupted clopidogrel group. 110 patients in interrupted clopidogrel group. The cumulative incidence of delayed post-polypectomy bleeding was 3.8% (95% CI 1.1% - 9.7%) in the uninterrupted clopidogrel group and 3.6% (95% CI 1.4% – 9.4%) in the interrupted clopidogrel group (log-rank test p = 0.945). Immediate post-polypectomy bleeding (8.5% versus 5.5%, p = 0.380) and cardiothrombotic events (1.5% versus 2%, p = 0.713) were noted.

Conclusion: Contrary to current guidelines, our study does not show any clinically meaningful increase of post-polypectomy bleeding with uninterrupted clopidogrel therapy in patients undergoing polypectomy. This study was supported by the Research Grant Council of Hong Kong [Grant number: 460912].

OPI37 EUS-GUIDED MULTI-MODALITY TREATMENT OF PERIPANCREATIC PSEUDO-ANEURYSMS
P. Somani1,2, M. Sharma1
1Jaswant Rai Speciality Hospital, Department of Gastroenterology, Meerut, India
2Thumby Hospital, Department of Gastroenterology, Dubai, United Arab Emirates

Contact E-Mail Address: dr_piyushsomani@yahoo.co.in

Introduction: Pseudoaneurysms may occur in both acute and chronic pancreatitis. Gastronianesthetic bleeding is the most common presentation after rupture. Pseudoaneurysms can be of different size and can have different wall thickness. Managing peripancreatic pseudoaneurysms is complex and challenging. Failure in radiological intervention is followed by surgery. We present a series of 6 cases of pseudoaneurysms from different anatomical locations.

Aims and Methods: All 6 patients were male. 4 patients presented with gastrointestinal bleeding. Delayed diagnosis was made in 2 cases. Initial management consisted of endoscopic therapy. The pseudoaneurysms were characterized by blood flow, size, and wall thickness. The treatment options were coil, thrombin, and glue injection.

Results: There were no major complications. All 6 patients had complete or near complete occlusion of pseudoaneurysm which was evaluated by abdominal ultrasound and endoscopic ultrasound. Multiple sessions were required 4 patients while 2 were treated with single session.

Conclusion: EUS guided treatment of pseudoaneurysms appears as effective, feasible and safe technique with many advantages. It is a minimally invasive procedure with minimal complications.

Introduction: Gastrointestinal haemorrhage by rupture of gastroduodenal varices has an incidence of 3 to 30% and represents approximately 10% of all upper gastrointestinal haemorrhages associated with portal hypertension (PHT). The aim of this work is to evaluate the therapeutic efficiency and complications of dilute chemical glue injection in glucose serum as an endoscopic haemostasis technique.

Aims and Methods: This is a retrospective study of 24 patients compiled between January 2012 and April 2018. All patients were admitted with upper gastrointestinal bleeding. They all had benefited from a gastrointestinal fibroscopy that had objectified bleeding caused by rupture of gastroduodenal varices. Methacryloxyethylsilicone-associated n-butyl-2-cyanoacrylate (Gibran 2) was prepared with glucose serum. The endoscopic treatment performed under sedation, consists of the injection of chemical glue at the level of gastroduodenal varices.

Results: The average age of our patients was 51 years [23 years -76 years]. A female predominance was noted, with a sex ratio F/M: 2.4. Glucose injection into gastric varice was performed in 21 patients (91.7%) of whom 12 had GOV2 (55%), 8 had GOV1 (36%), 2 had GOV1 (9%). Ectopic duodenal variceous veins were found in 2 patients (8.3%). The injection was performed at 1 or 2 sites of the ruptured varice. The initial haemostasis was obtained in 100% of cases. Recurrence was noted in 2 patients. No immediate or delayed complication was noted.

Conclusion: Our results confirm that endoscopic hemostatic treatment of hemorrhages from ruptured gastroduodenal varices by chemical glue diluted in glucose serum is effective and less expensive compared to dilution in Lipiodol which is not always available in our context.

Introduction: Portal venous system (PVS) is one of the most inaccessible systems of the body. Acute thrombosis of portal venous system, resulting in mesenteric ischemia has a high morbidity and mortality. Endoscopic ultrasound (EUS) guided access to the PVS is possible. We report EUS guided thrombolysis of acute portal venous system thrombosis in 6 cases.

Aims and Methods: Between December 2015 and march 2018, all symptomatic patients presenting with acute thrombosis of portal venous system with/without mesenteric ischemia were included in the study. Informed consent was taken. Diagnosis was achieved by clinical evaluation (abdominal pain, vomiting, abdominal distension) and CT abdomen (thrombus in PVS with/without abnormal thickening of ischemic bowel wall). Only patients without indication for surgery, i.e. bowel infarction, bowel perforation, were included. All patients had variable extent of acute thrombus along with dilated portal venous system and clinical features of impending mesenteric ischemia. All patients received intravenous fluids, antibiotics and low molecular weight heparin (LMWH). Patients without clinical improvement to anticoagulation therapy at 48 hours were taken for EUS guided thrombolysis.

Results: The portal venous system was possible by EUS-guided puncture and injection of streptokinase was given as continuous catheter thrombolysis with 30000 unit/hour in three cases. Bolus injections of 50000 units were given in portal vein, splenic vein and superior mesenteric vein in 3 cases. For bolus injection, the splenic vein was punctured from body of stomach, the portal vein was punctured from duodenal bulb and the superior mesenteric vein (SMV) was punctured from descending duodenum. For continuous catheter thrombolysis SMV was punctured through the pancreas with a 22 gauge EUS- FNA needle. A .018 inch guide wire was placed into a tributary of SMV. A tapered tip cannula was advanced over the wire and cannula was positioned in the tributary of SMV. The scope was removed while leaving the cannula in place, the cannula was tunneled through the nose and a syringe pump was fitted for infusion of thrombolytic agent. The thrombolysis was continued for 72 hours to 10 days depending on symptom improvement. Regular follow-up was done to monitor for GI bleed. The thrombolysis catheter was removed in all cases under endoscopic guidance to monitor for a possible bleed from catheter site.

Results: Procedure related: Technical success as defined by successful catheter placement in PVS was achieved in all patients (100%). During hospital course, 1 patient had catheter site bleed while catheter was in situ, for which hemostasis was achieved by inflating an enteroscope assisting device of balloon, fitted over the scope. 1 patient had mild oozes on catheter removal which was controlled by inflating an enteroscope assisting device of balloon fitted over the scope. 1 patient developed splenic infarct on day 7. Despite infarction, thrombolysis could be continued till the resolution of ileus on day 10.

Patient related: All patients tolerated the procedure well. All patients had resolution in pain and ileus. There was no mortality.

There was complete resolution of thrombus in 4 cases with partial resolution in 2 cases.

Conclusion: EUS-guided thrombolysis should be considered in life-threatening acute PVS thrombosis. Multicentre trials in larger number of cases are required and comparison with interventional radiology methods needs to be planned. We require dedicated accessories to ensure continuous delivery.

OPI40 FOOD-DERIVED BIOACTIVE PePTIDE: LUNASIN EXERTS AN IMMUNOMODULATORY ROLE IN THE HEALTHY HUMAN INTESTINAL MUCOSA

S. Fernandez-Tome1, P. Indiano-Romacho2, A.C. Marin1, L. Ortega-Moreno1, L. Perez-Rodriguez1, M.J. Casanova1, J.A. Moreno-Monteagudo1, C. Santander1, M. Chapparo1, J.P. Gisbert2, B. Hernandez-Ledesma2, D. Bernardo3

Introduction: The gastrointestinal mucosa represents the main interface between dietary components and the organism. Lunasin is a 43-amino acid peptide naturally present in soybean protein with a variety of biological functions demonstrated by in vitro assays, cell cultures and animal models. Nevertheless, its physiological relevance in human primary intestinal cells has been scarcely investigated.

Aims and Methods: Our aim, therefore, was to evaluate the ex vivo biological activity of peptide lunasin in the healthy human intestinal mucosa. peptide was obtained by chemical synthesis. Colonic biopsies from healthy controls were conditioned with peptide lunasin (5, 50, and 200 μM), both in the presence and absence of pro-inflammatory lipopolysaccharide (LPS). The cytokine milieu (IL-1β, TNF-α, MCP-1, IL-6, IL-8, IL-10, IL-12p70, IL-17A, IL-18, IL-23, and IL-33) was subsequently assessed on the culture supernatants following overnight culture. The stability and/or modification of peptide determined cultures was evaluated by liquid chromatography coupled to tandem mass spectrometry (HPLC-MS/MS).

Results: Peptide lunasin exerted immunomodulatory effects on the human intestinal mucosa determined by changes on the global cytokine milieu. While lungasin 5 μM was not bioactive, it regulated the cytokine profile at 50 μM expanding the production of IL-10 and IL-33 by intestinal mucosa. Moreover, at higher doses (lunasin 200 μM), this peptide lowered the production of IFN-γ, IL-6 and MCP-1, as well as enhanced an innate immune response characterized by upregulation of interleukin-1β and TNF-α cytokines. Nevertheless, this peptide did not modulate the global cytokine profile when intestinal mucosa was exposed to LPS. The response of colonic biopsies towards the conditioning with peptide lunasin was monitored by HPLC-MS/MS, confirming its presence during culture.

Conclusion: Bioactive food peptides may exert physiological effects related to digestive health given their direct and continuous contact with immune mucosa. Peptide lunasin modulated in resting conditions the immune cytokine profile of the healthy intestinal mucosa. This peptide might represent, therefore, a novel agent as functional compound for the prevention of immune and inflammatory-mediated intestinal disorders.

Introduction: Crohn’s disease (CD) is a chronic inflammatory characterized from an aberrant immune response favoring gut microbiota in genetically predisposed individuals and/or under the influence of environmental factors like a high-fat diet. In this context, CD is characterized by an abnormal ileal colonisation by adherent-invasive E. coli (AIEC) and an expansion of mesenteric adipose tissue (AT). Currently, immunosuppressive or biological treatments used in CD are not curative and have many side effects. In this context, physical activity (PA) could be an attractive alternative therapy through its anti-inflammatory properties, its ability to effectively decrease TA and favorably modulate the gut microbiota composition.

Aims and Methods: The aim of this study is to analyze the preventive effect of spontaneous PA on gut-adipose tissue cross-talk in CEABAC10 mice exposed by AIEC bacteria after training. 36 male CEABAC10 mice were divided in spontaneous PA (WHEEL; n = 24) and the control group (CONT; n = 12) during 12 weeks. The distance and the speed performed in WHEEL group were weekly recorded. After this period, both groups were exposed to AIEC LF 82 for 6 days and were killed 4 days later. Animals were fed with high fat/high sugar diet (HF/ HS) and study duration was a per feeding was performed on CONT group. Body composition was analyzed by EchoMRI and the weighing of tissue was realized post-mortem. Glycemic control was evaluated through fasting glycemia, insulinemia and an oral glucose tolerance test. The level of AT cytokines secreted (IL-6 and KC) was measured by ELISA. The expression of tight junction proteins (ZO-1 and occludin) was determined by western-blot and used as a marker of intestinal permeability. Gut microbiota was analyzed using 16S rRNA gene sequencing on an Illumina MiSeq Platform. Fecal short-chain fatty acids (SCFA) concentrations were determined using gas liquid chromatography.

Results: Over the 12 weeks, WHEEL group ran an average of 3.6 ± 0.4 km per day at an average speed of 8.5 ± 0.7 m/min. The total mean mass in WHEEL group was lower compared to CONT from week 7 to the end of protocol (p < 0.005). Total fat mass at 12 weeks was inferior in WHEEL group compared to CONT group (p < 0.05). Before bacterial exposition, glycemic control (fasting glycemia, insulinemia and plasma glucose OGTT response) were not affected by spontaneous PA, however, the distance run and the speed were associated with lower fasting glucose and an increase of glucose tolerance (p < 0.005). Mesenteric AT was lower in WHEEL group, and a negative correlation was found between mesenteric AT and distance ran (r = 0.6, p < 0.05). Tight junction protein content increased in the WHEEL group. Beneficial and anti-inflammatory genera (Bifidobacterium and Lactobacillus) in CONT group decreased while the AP favors slimming-related genera (Oscoolispora) and SCFA producers (Ruminococcus). Concomitantly, proportionate and butyrate were higher in the WHEEL group (p < 0.05).

Conclusion: Spontaneous PA favors a modification of the gut microbiota composition of CEABAC10 mice in response to HF/HS diet and bacterial exposition. This modification could be related to the decrease of total fat mass and more accurately to the mesenteric AT reduction. These effects were greater when the average distance performed and the mean speed were higher. These preliminary results obtained in a rodent model could be expanded to patients with CD in therapeutic clinical protocols. Physical activity could then be considered in patients with CD in order to substantially improve their quality of life.

Introduction: Genome-wide association studies identified many risk genes for inflammatory bowel disease (IBD).1 Amongst these, many genes encode proteins that are involved in proteostasis, including endoplasmic reticulum (ER) stress. Understanding how such defects in proteostasis induce anti-inflammatory protective responses could lead to novel therapy.2 An important mechanism of protection in the intestine is the production of Immunoglobulin A (IgA) by plasma cells.2 Interestingly, plasma cell accumulation around the intestinal crypts, so-called basal plasmacytosis, is a phenomenon often observed in inflammatory bowel disease.

We set out to investigate whether ER stress induces protective IgA responses. Aims and Methods: To model the role of ER in the intestine, mice were developed in which X-box binding protein-1 is deleted specifically in the intestinal epithelium (Xbp1-/-). IgA deficient (IgA−/−), B cell deficient microT mice, and TCRb deficient (TCR−/−) mice were crossed to Xbp1-/- mice to generate double KO (Xbp1−/−;MT mice, and TCR−/−Xbp1−/−;B cell deficient animals generated by injection of females at a gestational day 13.5 with anti-IgM antibodies which abrogates PP ontogeny. Germ free (GF) Xbp1−/−;MT mice were generated as previously described.

Intestinal lamina propria (LP), Peyer’s patch (PP) and peritoneal immune cell populations were studied using flowcytometry and immunohistochemistry.

Introduction: Mesenchymal stem cells (MSCs) transplantation is a promising strategy for inflammatory bowel disease (IBD). However, low cell retention and engraftment after transplantation diminish the clinical application of MSCs in IBD. In our previous report, a synthesized bioactive hydrogel by immobilizing the C domain peptide of insulin-like growth factor-1(IGF-1C) on chitosan formed a hydrogel matrix which can refresh stem cells by mimicking niche. Hence we aim to investigate whether co-transplanting this hydrogel with human placenta-derived mesenchymal stem cells (hP-MSCs) into the damaged colon could ameliorate trinitrobenzene sulfonic acid (TNBS)-induced colitis and illustrates its mechanism.

Aims and Methods: Utilizing the lentivirus transfected into hP-MSC which stably express fireflyluciferase (Fluc) and green fluorescent protein (GFP) thereby can be measured proliferation effect of CS-IGF-1C hydrogel for hP-MSCs and tracked by bioluminescence imaging (BLI) and histology, respectively. Colitis was induced with TNBS via enema, mesenteric injection of PBS, chitosan hydrogel, or chitosan-IGF-1C hydrogel with hP-MSCs or PBS without hP-MSCs were performed. After living imaging by BLI for measuring the survival of hP-MSCs and reactive oxygen species (ROS), intestinal tissues were collected for pathological analyses. Interleukin-1 (IL-1) and interleukin-6 (IL-6) were tested by real time PCR. Western blot and immunofluorescence analyses are conducted for detecting the phenotype of macrophages after transplantation. Enzyme linked immunosorbent assay (ELISA) was performed for testing PGE2 from the supernatant of hP-MSCs.

Results: Comparing with free hydrogel or chitosan hydrogel only, the CS-IGF-1C hydrogel significantly increased stem cell proliferation demonstrated by BLI. Moreover, in vivo studies indicated that CS-IGF-1C hydrogel promoted hP-MSCs survival confirmed by BLI and co-transplantation of CS-IGF-1C hydrogel with hP-MSCs alleviated intestinal inflammation, achieved histological improvement compared with free hydrogel or chitosan hydrogel only. Additionally, CS-IGF-1C hydrogel could promote hP-MSC releasing PGE2, polarizing M2 macrophages accompanying expression of Interleukin-10 (IL-10) furthermore reducing the level of M1 macrophages in vitro and in vivo.

Conclusion: Topical application of CS-IGF-1C hydrogel implanted hP-MSCs significantly ameliorates mouse colitis via promoting these donor cells releasing PGE2, which polarizes M2 macrophages accompanying IL-10 expression. To our knowledge, this is the first report on co-transplantation with CS-IGF-1C hydrogel and MSCs on IBD as well as the local-injection as administration which improve the therapeutic effectiveness of MSCs on TNBS-induced colitis significantly. These data could benefit the expansion of application of MSCs transplantation in inflammatory bowel disease.

Introduction: Cron’s disease (CD) is a chronic remittent inflammatory condition of the gastrointestinal tract that arises from a deranged interplay of the immune system, microbiota and unknown environmental factors in genetically susceptible hosts. GWAS studies recently revealed a genetic association of glutathione peroxidase 4 (GPX4) with the development of CD (1). Reduced GPX4 activity leads to a form of iron-dependent regulated cell death that is termed ferroptosis. Recent findings linked ferroptotic cell death with incorporation of polyunsaturated fatty acids into biological membranes, including arachidonic acid (AA) (2). AA is contained within a western style diet and especially animal products. The consumption of these fatty acids paralleled the increased IBD incidence in the last decades. However, the role played by AA in intestinal inflammation is unknown.

Aims and Methods: In this study we aimed to investigate the influence of AA on intestinal epithelial cells, with reduced GPX4 expression evoked by siRNA silencing. For in vitro analysis we crossed Gpx4+/− (mice with Villin-Cre+/− mice to Gpx4+/− mice) with Villin-Cre+/+. Gpx4+/− mice showed dysregulated inflammatory phenotype in Gpx4-deficient murine MODE-K small intestinal epithelial cells (IEC) and organoids from Gpx4+/− mice upon AA treatment. Results: IECs that were Gpx4 silenced, showed increased lipid peroxidation and febriportotic form of cell death was induced by AA. Ferroptosis was paralleled by production of IL-6 and the IL-8 homologue CXCL1. Cytokine production and proximal small intestine as well as increased CXCL-1 expression, while wildtype challenged with AA and ferric maltol showed neutrophilic infiltration in the inflamed and ulcerated mucosa of DSS-treated mice. ST2 staining was more evident during the recovery phase following DSS, mostly localized to IEC and SEMF in close proximity to areas of epithelialization. Both IL33 and ST2 deficiency in mice reduced the severity of colitis after acute DSS, but interestingly dampened epithelial repair throughout the recovery period in WT. IL-33 treat- ment during recovery decreased endoscopic and histologic score, promoting mucosal regeneration, a faster body weight recuperation and disease activity ameliora- tion vs. VEH. ATX and scratch assay, IL-33 significantly increased cell pro- liferation and wound healing vs. untreated Caco-2 cells. Microarray analysis showed IL-33-mediated activation of intracellular proliferative pathways. In par- ticular, IL-33 administration potently upregulated miR-320 vs. untreated cells. These results were confirmed at qPCR in both Caco-2 vs. untreated cells and IECs isolated from IL-33 treated mice vs. VEH. Specific knockdown of MIR320 significantly decreased both epithelial proliferation and wound healing vs. Control at ATX and scratch assay, respectively.

Conclusion: Taken together, IL-33 can play a dichotomous role during gut muco- sal inflammation, stimulates epithelial restitution and repair, and promotes over- all recovery during colitis potentially through a mechanism involving upregulation of miR-320.

Small bowel disorders – Room N2

OP147 CHRONIC INTESTINAL FAILURE: WHEN CHILDREN BECOME ADULTS

L. Schubert, V. Boehm, F. Joly, L. Billiauws

Beaujon Hospital, Gastroenterology and Nutrition Support, Clichy, France

Contact E-Mail Address: francisca.joly@gmail.com

Introduction: Major advances in recent years have resulted in improved survival for patients with chronic intestinal failure (CIF). There is very little data on the future of children that became adult with CIF.

Aims and Methods: The aim of our work was to describe this population since the creation of our center.

Results: After an approved HPN centre for adults with a dedicated activity for CIF, we collected retrospectively all data related to patients treated with home parenteral nutrition during infancy (at least 4 years before transition to our centre) and transferred in our centre since 1984. We evaluated demographic data, social evolution and certain complications at adulthood. Results were expressed as median [IQR].

Results: Among a total of 870 HPN patients followed between 1984 and decem- ber 2017, 44 young adults (17/27M) were transferred from 3 paediatric hospi- tals. Age of transition was 19±2 years. The principal etiologies of CIF were short bowel syndrome (n = 18), CIPD (n = 21), mucosal disease (n = 5). At the end of follow up, defined as the last news or death, 7/44 patients had died (2 after intestinal transplantation, 3 after sepsis, 2 due to liver failure), 3/44 were weaned off PN (2 due to growth factors, 1 after intestinal transplantation), 33/44 were alive requiring HPN: (6±1.7 infusions/week; 2.2±1.3 day/s; 29±13 kcal/kg/day). Oral intake was 2000±105 kcal/day but 9/44 presented remaining oral disor- ders. Seventeen/44 had a regular work (35±6 hours/week), 23 lived with their parents; 17 lived in partnerships and had at least one child.

Conclusion: Despite progress in survival and quality of life in HPN, many chil- dren who become adults stay with their parents and do not work. The transition requires probably a better social, educational and psychological preparation if we want to improve the future of these patients.

OP148 OUTCOMES OF TREDUGLUTIDE TREATMENT AT 6 MONTHS IN ADULTS WITH SHORT BOWEL SYNDROME AND CHRONIC INTESTINAL FAILURE: A NATIONWIDE FRENCH PROSPECTIVE OBSERVATIONAL COHORT STUDY

F. Joly1, D. Quilliot2, A. Zuzzo1, P. Beauf1, C. Chambrier2, F. Poullenot1, L. Armenoegl Debie2, S. Layec1, R. Thibault1, V. Boehm1, D. Seguy1, S. Schneid1
1Beaujon Hospital Service de Gastroenterologie, Gastroenterology, Clichy, France
2CHU Nancy, Nancy, France

Introduction: Short bowel syndrome with intestinal failure (SBS-IF) is a rare condition that requires parental support (PS). Prolonged trials with teleduglute (TED) in SBS-IF have demonstrated a PS volume reduction ≥20% from baseline (BL) in 63% of treated patients at 6 months (M6). In France, TED has been available since October 2015, and initial results demonstrated an early response and a ≥40% of patients were weaned-off PS. The objectives of the current analysis are to evaluate the real-world setting the outcomes of treatment and to assess the predictive factors of response and of PS wean-off at M6 in adults with SBS-IF.

Aims and Methods: This is a French, multicenter, observational study looking at the clinical status and outcomes of all adult patients with SBS-IF who have initiated TED (N=74). All patients on treatment for ≥6 months between October 2015 and September 2017 are included in this analysis (n=54). Clinical response is defined as ≥20% of PS volume reduction from BL at Week 24 of treatment. Descriptive summary statistics are presented as mean (range) values, and univariate analysis adjusting for nutritional variables (age, sex, body weight) have been conducted to identify predictors of response and of PS wean-off.

Results: 54 patients with SBS-IF were treated with TED (0.03 mg/kg/day) for ≥6 months. 22 (40.7%) were women, age was 52.3 years (range, 22–83). PS duration was 9.8 years (range, 0.5–31), PS days/week was 4.3 (2–7). PS volume was 11,163 mL/week (range, 2000–38,500), and oral energy intake was 6347 kcal/week (range, 0–16,800). 19 patients (35%) had a jejunostomy, 27 (50%) a jejunoduodenostomy, and the remaining 8 patients had colostomies. Clinical response was observed in 37/54 patients (68.5%). The predictive factors of wean-off at M6 were a jeunutopic response (p=0.007), a low PS volume at BL (p=0.001), a high oral energy intake (p=0.018).

Conclusion: This is the largest real-world adult cohort with SBS-IF treated with TED. The results of this analysis confirm the findings from the Phase II study. Our study shows that net volume PS reduction is higher for patients with high baseline PS while all types/causes of SBS may benefit from TED with a similar relative reduction in PS needs. Furthermore, patients with colon in continuity, low baseline PS volume requirements and high oral intake are most likely to fully wean-off PS.

OP150 PROTEIN-LOSING ENTEROPATHY AFTER FONTAN SURGERY IS ASSOCIATED WITH LIVER DAMAGE AND HIGH LEVELS OF FECAL CALPROCTIN: A CASE-CONTROL STUDY FROM A PROSPECTIVE DATABASE

L. Téllez1, E. Rodriguez de Santiago2, E. Garrido Lestache3, L. Aguilara Castro4, A. Olavarria5, E. Garrido6, F. Gea Rodríguez7, R. Romera8, M.J. Del Cerro9, Agustín Martínez2
1Hospital Universitario Ramón y Cajal, Gastroenterology and Hepatology, Madrid, Spain
2Hospital Universitario Ramón y Cajal, Pediatrics Cardiology, Madrid, Spain
3Hospital Universitario Ramón y Cajal, Radiology, Madrid, Spain

Introduction: The Fontan procedure is used in patients with a single functioning ventricle due to a complex congenital heart disease. This results in sustained systemic venous hypertension that in the long term cause liver damage and, in some patients, protein-losing enteropathy (PLE). The association between liver disease and PLE is unknown. Additionally, PLE is thought to be associated with intestinal inflammation. However, data supporting this hypothesis is scarce and fecal calproctin (FC) has not been assessed in this population.

Aims and Methods: We aimed to evaluate if PLE is associated with liver damage through non-invasive methods and to assess if FC is increased in PLE. This is a case-control study from an unicentric prospective-database. Patients were evaluated by blood tests; Fibroscan®; abdominal Doppler-US, MRI or CT (if pectus excavatum); and echocardiography and other cardiological test. PLE was defined as Alpha-1-Antitrypsin clearance > 27 ml/day. Controls were matched by age and Fontan procedure (atriopulmonary/extracardiac). IBD was an exclusion criteria. Univariate analysis using non-parametric tests with adjustment for multiple comparisons was performed.

Results: 14 cases and 15 controls were included. Baseline and cardiological characteristics are detailed in Table 1. Patients with PLE presented worse cardiological function. Non-invasive methods suggested more advanced liver disease in PLE (median: p<0.01) with 20 events of diarrhoea (14 lanreotide vs. 6 placebo; p<0.05) with 20 events of diarrhoea (14 lanreotide vs. 6 placebo; p<0.05). All 7 serious AE occurred during lanreotide treatment (25.4 vs 14.5 Kpa, p=0.03), ascites in US (43% vs 7%, p=0.03), esophageal varices or intrabdominal collateral circulation on CT/MRI (64.3% vs. 33.3%, p=0.03), FIB-4 index (1.4 vs 0.9, p=0.016) and LSPS index (2.2 vs 0.38, p<0.05). No differences were detected in bilirubin, transaminases or cholesterol levels.

PLE patients had higher FC values (median) (80 vs 30 µg/g; p<0.001). No differences were found in NSAID, anticoagulants or antaggregants consumption. Calproctin levels were directly correlated with alpha-1 antitrypsin clearance (rho=0.6, p=0.004) and inversely with the cardiac index (rho=-0.65, p=0.006), total proteins (rho=-0.68, p=0.004) and the body mass index (rho=-0.5, p=0.01).

Conclusion: 1. PLE is associated with more advanced liver disease.
2. Fecal calproctin is increased in PLE and correlates with its severity. Our study suggest that FC could be a useful biomarker in PLE after Fontan surgery.

OP151 ORAL ANTIBIOTICS PREVENT INTESINAL NECROSIS IN ACUTE MESENTERIC ISCHEMIA: A PROSPECTIVE COHORT STUDY

A. Nuzzo1, L. Maggiori2, D. Cazals-Hatem1, C. Paugam-Burtz1, A. Huquet1, M. Ronot1, A. Becq1, Y. Casier1, E. Weis1, F. Joly1, Y. Panis1, Y. Bouhnik1, N. Gault1, O. Corcos1

Introduction: The high mortality of acute mesenteric ischemia (AMI) closely correlates with the occurrence of intestinal necrosis leading to extensive intestinal resection. It is showed that a multi-organ and multidisciplinary man-agemnt of AMI, including a prompt revascularization, decreased the overall mortality as well as the rate of intestinal resection in this setting. These results demonstrated that AMI is potentially reversible and that preventing its progres-sion to irreversible transmural intestinal necrosis (ITIN) should be a primary therapeutic goal. Alongside prompt revascularization, other treatments may help avoid, limit or delay ITIN and its complications. The aim of this study was to assess the efficacy of these therapeutic measures in terms of their effect on the occurrence of ITIN.

Aims and Methods: We conducted a prospective observational cohort study in our intestinal stroke center including all consecutive patients admitted for AMI between January 1st, 2009 and December 31st, 2014. The primary outcome was the occurrence of pathologically proven ITIN in patients who underwent surgery within 90 days from admission. Patients with superficial and non-transmural ischemic necrosis upon pathological assessment and those who recovered from AMI without need for surgery were also considered not to have ITIN. Resected specimens were retrospectively reviewed in order to confirm ITIN by a senior pathologist, expert in gastrointestinal diseases and blinded to the treatments administered before surgery. The origin of AMI, epidemiological and clinical data as well as treatment provided (oral and/or IV antibiotics, antibiotics against intestinal micro-organisms, revascularization and delays) were collected. A Cox regression model with time-dependent variables was performed for statistical analysis.

Results: A total of 67 patients [29 (43%) women; median age 54 (40-63) years] were included. The origins of AMI were arterial, venous, mixed and non-ooclusive in 52%, 37%, 6% and 2% of cases, respectively. Pharmacological treatment immediately provided upon admission included intravenous antibiotics (n = 53; 79%), oral analgesic therapy (n = 37; 55%), anticoagulant therapy (n = 65; 94%), antiplatelet (n = 29; 83% of arterial AMI patients), and revascularization therapy (n = 18; 51% of arterial AMI patients). Median follow-up was 12 months [95% confidence interval (CI) = 9.6-21.7]. 28 (42%) patients underwent intestinal resection and ITIN was noted in 23 (34%) of cases. In multivariate analysis, oral antibiotics was associated with a significant decrease in the risk of ITIN [HR: 0.16 (95%CI = 0.03-0.62); p = 0.01] whereas organ failure was associated with an increased risk [HR: 15.4 (95%CI = 3.2-73.7); p = 0.001]. Overall mortality was 33% and ranged from 2% to 35% in patients without and with ITIN, respectively.

Conclusion: Our results suggest a protective effect of oral administration of antibiotics against the occurrence of irreversible transmural intestinal necrosis in the setting of AMI. A management strategy including at least oral antibiotics in addition to early revascularization might reduce or prevent progression of AMI to intestinal necrosis, avoid surgery and improve survival. Such a strategy should be confirmed with further prospective interventional studies.

Disclosure: MSD Avenir grant

OP152 BOWEL PREPARATION FOR SMALL BOWEL CAPSULE ENDOCOSOPY – THE LATER, THE BETTER!

S. Xavier1,2,3, C. Lages Gonçalves4, B. Rosa4, S. Monterro2,3, C. Arierra4, R. Magalhães2,3, A. C. Guimarães2,3, R. Pires2,3,4

Contact E-Mail Address: bruno.joel.rosa@gmail.com

Introduction: In small bowel capsule endoscopy (SBCE), the presence of residue in the small bowel lumen limits the observation, hampers the interpretation and may lead to diagnostic mistakes.

Aims and Methods: We aimed to assess differences in the diagnostic yield of SBCE using 3 different preparation protocols, as well as the rate of complete examinations and small bowel transit time (SBTT).

Prospective, randomized, blind study, including 101 patients that consecutively preformed SBCE (PillCam® SB3, Given Imaging). Protocol A: Clear liquids diet the day before the examination with fasting from 8 pm.; Protocol B: Protocol A + 2 pouches of Moviprep® (polyethylene glycol electrolyte solution) in 1 liter of water from 8p.m. of the day before the examination; Protocol C: Protocol A + 2 pouches of Moviprep® in 1 liter of water to be consumed after real-time confirmataion of SBCE arrival at small bowel.

Small bowel preparation was classified by an experienced physician, considering the percentage of the examination in which mucosal observation was adequate: Excellent (>90%), Good (90-75%); Fair (75-50%); Poor (<50%).

Results: 101 patients were randomized to the 3 protocols (A: 37, B: 31 and C: 33 patients). Protocol C had an excellent or good small bowel preparation in a higher percentage of examinations (A: 37.8% vs B: 45.2% vs C: 78.8%, p = 0.002). No significant differences were found between the 3 protocols regarding the transit time (A: 378+/−197 minutes vs B: 334+/−197 minutes vs C: 344+/−148 minutes = 0.904) or complete examinations rates (A: 89.2% vs B: 100.0% vs C: 93.9%, p = 0.171).

Conclusion: In SBCE the administration of Moviprep® after the confirmation of capsule arrival at the small bowel associated with a better small bowel prepara-tion and a higher detection of angiectasia. Therefore, this innovative protocol should be systematically used to improve procedure results.

Murine models of intestinal inflammation – Room L7

OP153 LOSS OF PTPN2 IN DENDRITIC CELLS PROMOTES T CELL ACTIVATION AND DIFFERENTIATION INTO TH1 CELLS BUT DOES NOT AFFECT REGULATORY T CELLS

E. Hering1, E. Katkeviciute1, C. Gottler1, S. Lang1, B. Becker1, G. Rogler1, M. Schütz1, M.R. Spalinger1

1University Hospital Zürich, Department of Gastroenterology and Hepatology, Zürich, Switzerland
2University of Zürich, Institute of Experimental Immunology, Zürich, Switzerland

Introduction: Variants within the gene locus encoding protein tyrosine phosphatase non-receptor type 2 (PTPN2) are associated with the development of inflam-matory disorders, including IBD. The role of PTPN2 in T cells and intestinal epithelial cells has been investigated in depth, but its role in dendritic cells (DCs) remains unclear. Understanding the DC specific role of PTPN2 is of particular interest, since DCs play a crucial role in activation of T cells and orchestrating immune responses in general. Here, we addressed whether loss of PTPN2 in DCs affects the expression of co-stimulatory molecules and subsequently activation and differentiation of T cells.

Aims and Methods: Mice with a LoxP flanked PTPN2 gene were crossed with mice expressing Cre-recombinase under control of the CD11c promoter in order to specifically delete PTPN2 in DCs (PTPN2-CD11cCre mice). Using multico-lour flow cytometry, we analysed immune cells in the spleen, mesenteric lymph nodes, lung, liver, kidney, and skin in PTPN2-CD11cCre mice and their wild-type littermate controls.

Results: PTPN2-CD11cCre mice show symptoms of splenomegaly and skin inflammation, as well as increased infiltrates in the liver and lung in some mice. Severity of the inflammation varies between individuals, resulting in spon-taneous death in some mice. We found increased expression of co-stimulatory molecules CD80 and CD86 on PTPN2-deficient DCs. Of note, there was no difference in the expression of MHCI or CD11c in DCs from PTPN2-deficient mice compared to wild-type littermate controls. Consistent with increased expression of co-stimulatory molecules, we observed increased numbers of CD80+T cell memory; CD4+Th1 cells in both DCs from PTPN2-CD11cCre mice and their littermate controls. Further, increased expression of co-stimulatory molecules was noted in CD80+T cell memory; CD4+Th1 cells in both DCs from PTPN2-CD11cCre mice and their littermate controls.

Conclusion: In conclusion, our results show that PTPN2 has an important anti-inflamma-tory role in DCs. Loss of PTPN2 in DCs promotes T cell activation as well as increased expression of co-stimulatory molecules CD80 and CD86. Further, it affects differentiation into Th1 but not Th2 or Th17 T cells. However, PTPN2 in DCs does not affect gamma delta T cells. Further studies will investigate the interaction of PTPN2-deficient DCs and T cells in terms of antigen presentation and subsequent T cell proliferation and differentiation.

OP154 MURINE MODELS OF INTESTINAL INFLAMMATION – ROOM L7

PTPN2-CD11cCre mice show symptoms of splenomegaly and skin inflammation, as well as increased infiltrates in the liver and lung in some mice. Severity of the inflammation varies between individuals, resulting in spontaneous death in some mice. We found increased expression of co-stimulatory molecules CD80 and CD86 on PTPN2-deficient DCs. Of note, there was no difference in the expression of MHCI or CD11c in DCs from PTPN2-deficient mice compared to wild-type littermate controls. Consistent with increased expression of co-stimulatory molecules, we observed increased numbers of CD80+T cell memory; CD4+Th1 cells in both DCs from PTPN2-CD11cCre mice and their littermate controls. Further, increased expression of co-stimulatory molecules was noted in CD80+T cell memory; CD4+Th1 cells in both DCs from PTPN2-CD11cCre mice and their littermate controls.
OP154 LACK OF SUCNR1 PROTECTS FROM INTESTINAL FIBROSIS

1FISABIO, Hospital Dr. Peset, Valencia, Spain
2Department of Medicine, University of Valencia, Valencia, Spain
3Department of Medicine, University of Valencia, Valencia, Spain
4Department of Gastroenterology, Universitätsklinikum der Universität Würzburg, Würzburg, Germany

Disclosure: Nothing to disclose

Introduction: Intestinal fibrosis is a common complication associated with Crohn’s Disease (CD) which cannot be reverted with any drug and forces repeated surgery. It has been reported that succinate, a metabolite accumulated in inflammatory pathologies, plays an important role in the activation of synovial fibroblasts and hepatic stellate cells through its receptor called SUCNR1 or GPR91.

Aims and Methods: We aim to analyse the relevance of SUCNR1 receptor in intestinal fibrosis. Intestinal resections from CD patients and colon carcinoma patients were obtained and the expression of SUCNR1 and α-sma were analysed by immunostaining. Primary intestinal fibroblasts from human resections or from colon of wild-type (WT) or SUCNR1−/− (KO) mice were isolated, maintained in culture and treated with different concentrations (0, 0.1, 0.5, 1, 5 mM) of succinate for 24 hours. Intestinal fibrosis was induced in vivo introducing one intestinal graft from WT or KO mice into the neck of a receptor mice for 7 days. The expression of pro-fibrotic markers was analysed by qPCR. Sirius Red staining was performed and the collagen layer was quantified using ImageJ. Results are expressed by mean ± SD (n=5). Statistical analysis was performed with one-way ANOVA followed by Newman-Keuls test. Correlations were analysed with the Spearman coefficient.

Results: SUCNR1 is expressed in epithelial cells and α-sma+ cells of intestinal resections from CD patients. The SUCNR1 expression positively and significantly correlates with the expression of α-sma (r=0.759, p<0.001, n=24) and collagen α1S (r=0.82, p<0.001, n=24). In primary fibroblasts isolated from CD patients (13.54±4.6) the expression of SUCNR1 was significantly higher than in those obtained from control patients (2.07±0.86). In these cells, succinate induced the expression of profibrotic markers such as COL1A1, α-sma, Tgfb, and TIMP1 in a dose-response manner. This pro-fibrotic effect of succinate was also observed in fibroblasts from WT mice and it was completely reverted in fibroblasts from GPR91−/− mice and treated with different concentrations (0, 0.1, 0.5, 1, 5mM) of succinate in a dose-response manner. This pro-fibrotic effect of succinate was also observed in fibroblasts from WT mice and it was completely reverted in fibroblasts from GPR91−/− mice and treated with different concentrations (0, 0.1, 0.5, 1, 5mM) of succinate for 24 hours. Intestinal fibrosis was induced in vivo introducing one intestinal graft from WT or KO mice into the neck of a receptor mice for 7 days. The expression of pro-fibrotic markers was analysed by qPCR. Sirius Red staining was performed and the collagen layer was quantified using ImageJ. Results are expressed by mean ± SD (n=5). Statistical analysis was performed with one-way ANOVA followed by Newman-Keuls test. Correlations were analysed with the Spearman coefficient.

Conclusion: An increased expression of SUCNR1 receptor is detected in fibroblasts from CD patients the activation of which induces a pro-fibrotic effect. This receptor mediates murine intestinal fibrosis and we propose its blockade as a new pharmacological target in CD treatment.

OP155 RELEASE OF UNCONTROLLED ACTIVE ELASTASE BY INTESTINAL EPITHELIAL CELLS PARTICIPATES TO MUCOSAL INFLAMMATION IN IBD

1Digestive Health Research Institute, Toulouse, France
2CHU Toulouse, Toulouse, France
3Fédération Digestive, Toulouse, France

Disclosure: Nothing to disclose

Introduction: Imbalance between proteases and their inhibitors appears to be crucial to the development of Inflammatory Bowel Diseases (IBD). We have previously shown that colonic biopsies from IBD patients released higher elastolytic activity compared to biopsies from healthy controls. In addition, expression of ELAFIN, an endogenous elastase inhibitor, was significantly down-regulated in mucosa from IBD patients, compared to healthy controls.

Aims and Methods: The aim of our study was to identify the source of elastase hyperactivity released by IBD biopsies and to examine its impacts on colonic barrier function and inflammatory response. In situ zymography with FITC-elastin was performed on cryosections of colonic biopsies from healthy and IBD patients taken from inflamed and non-inflamed areas. Immunostaining for epithelial elastase was performed on cryosections from human biopsies, human organoids, or from mouse colon. A Ca2+ dependent epithelial cell line expressing and secreting elastase (Tg-ELA) was constructed and the potential of elastase hyperactivity to modulate the release of cytokines and permeability changes was evaluated. Transgenic murine model, which over-expressed the epithelial elastase specifically in epithelial cells in a temporally controlled manner, was developed (pVillin-CREERT2-ELA) and analysed at macroscopic and molecular levels.

Results: In situ zymography evidenced strong elastolytic activity in enterocytes of healthy human colonic tissues, which was greatly enhanced in inflamed biopsies as well as in non-inflamed biopsies from IBD patients. An elastase cDNA was cloned from human enterocytes. Immunostaining of colonic tissues showed that this elastase was only expressed in epithelial cells and secrreted into the lumen. In IBD, the expression of this elastase was enhanced in the epithelium. Tg-ELA epithelial cells exhibited defective barrier function accompanied by an increase of pro-inflammatory cytokine expression. Western blot analyses revealed that the major elements of tight junction, Occludin and Claudin-1, were targeted by elastase hyperactivity secreted in the medium. In addition, in vivo, over-expression of elastase in the intestinal epithelium (pVillin-ELA mice) for 5 weeks led to increased permeability and overexpression of antimicrobial peptides (Reg3g and Reg3b). Macrophage damage scoring highlighted intestinal inflammation, with strong adhesion phenotype.

Conclusion: We demonstrate the presence of an epithelial form of elastase in the intestine. Imbalance between elastase and its inhibitor in the epithelium participates in the generation of IBD-associated symptoms.

Disclosure: Nothing to disclose

OP156 LOSS OF PTPN2 IN DENDRITIC CELLS RESULTS IN REDUCED TUMOR BURDEN IN THE AOM/DSS COLON TUMOR MOUSE MODEL

E. Katkeviciute1, L. Hering1, M. Scharf1, M.R. Spalinger1
1University Hospital Zürich, Department of Gastroenterology and Hepatology, Zürich, Switzerland

Disclosure: Nothing to disclose

Introduction: Protein tyrosine phosphatase non-receptor type 2 (PTPN2) has recently been identified as potential cancer immunotherapy target. We have previously recognised PTPN2 as a key regulator for inflammatory responses in the intestine. Our recent data demonstrate that loss of PTPN2 in myeloid cells using PTPN2LysMcCre conditional PTPN2 knock-out mice results in reduced tumour burden in the azoxymethane (AOM)-dextran sodium sulphate (DSS) induced model of colitis-associated colorectal cancer. However the role and mechanism of action of PTPN2 in colon carcinoma development has not yet been studied in detail. Here, we showed that the tissue specific loss of PTPN2 in dendritic cells results in reduced tumour load in AOM/DSS mouse model.

Aims and Methods: We generated a mouse line lacking PTPN2 specifically in dendritic (PTPN2−/−CD11cCre) cells. We then induced colon tumour formation in wild-type (WT) and PTPN2-deficient mice using the AOM/DSS model of colitis-associated cancer and analysed immune cells in spleen, mesenteric lymph nodes (LN) and lamina propria in PTPN2−/−CD11cCre and their WT littermate controls using flow cytometry and RNA expression levels.

Results: AOM/DSS treatment resulted in the formation of colon tumours in both WT and KO mice. Tumour burden varied between individual mice, however PTPN2−/−CD11cCre mice had less and smaller tumours comparing to their WT treated and untreated groups. This effect is likely mediated via promoting anti-cancer immune responses by modulating checkpoint inhibitor molecule expression.

Conclusion: In conclusion, our results demonstrate a role for PTPN2 in the pathogenesis of colorectal carcinoma in vivo. Loss of PTPN2 in dendritic cells exerts anti-tumour effect and results in lower colon tumour burden in AOM/DSS treated mice. This effect is likely mediated via promoting anti-cancer immune responses by modulating checkpoint inhibitor molecule expression.

Disclosure: Nothing to disclose
Introduction: In colitis-associated cancer (CAC), tumor protein p53 (TP53) mutation often occurs in the early phase of colon carcinogenesis known as dysplasia-carcinoma sequence. Although there are some reports about the relation between TP53 mutation and colonic carcinogenesis in mice model, a direct effect of TP53 mutation on colon epithelial cells and carcinogenesis in human are still unknown. We therefore aimed to assess the influence of TP53 mutation by using a CRISPR Cas9 system on human colon epithelial organoids under long-term inflammation model which we originally launched.

Aims and Methods: TP53 mutation was generated by using lentiviral CRISPR Cas9 system in 3 different epithelial organoids derived from individual human colon mucosa with wild-type TP53 (WT-TP53). Written informed consent was obtained from all included patients and this study was approved by the Ethic Committee of Tokyo Medical and Dental University. The guide RNA was designed to bind exon 10 of TP53. TP53 mutation in organoids was confirmed by direct sequencing. The expression of TP53 protein was assessed by immunohistochemical detection of TP53 with antibody by NewMillennium and the expression of TP53 target genes. Gene expression was assessed by microarray analysis and quantitative PCR. The long-term inflammation model was established by culturing organoids with inflammatory factors (TNF-α, Flagellin and IL-1β) for 2-10 weeks. Inflammatory response in the organoids was assessed by gene expression of inflammatory-related genes and the level of reactive oxygen species (ROS). Phenotypes of each organoids were assessed by MTS Assay, sphere formation assay for cell proliferation and stemness, respectively.

Results: At first, we successfully established TP53 mutation in 3 different human colon epithelial organoids. Mutant TP53 was strongly expressed in nuclei of all organoids as shown in dysplastic lesion of ulcerative colitis (UC), whereas WT-TP53 was not expressed in naive organoids. Mutant TP53 also showed Nutilin-resistance and down-regulation of TP53 target genes, indicating the loss of function of TP53. Moreover, microarray analysis revealed up-regulated genes in the organoids with mutant TP53, suggesting the gain of specific function of mutant TP53. We then assessed the effect of mutant TP53 with or without inflammatory stimulation for 60 weeks. Long-term inflammatory stimulation attenuated cell proliferation and sphere formation of the organoids with WT-TP53. Mutant TP53 however enhanced cell growth and stemness with increased gene expression of c-myc and Lgr5 compared to WT-TP53 under the inflammatory situation, nevertheless inflammatory response in the organoids with mutant TP53 was equal to that in the organoids with WT-TP53.

Conclusion: We for the first time showed TP53 mutation alone enhances cell proliferation and stemness of human colon organoids under long-term inflammation. Mutant TP53 cancelled epithelial cell damage induced inflammation, suggesting that these results might mimic the early step of colitis associated carcinogenesis.

Disclosure: Nothing to disclose
associated symptoms (hypersensitivity and barrier defects), and could constitute a new target for the treatment of colonic hypersensitivity.

Disclosure: Nothing to disclose.

OP160 NO UNCONSCIOUS ATTENTIONAL BIAS FOR GI-SALIENT TERMS IN SUBJECTS WITH FUNCTIONAL GI DISORDERS: OBJECTIVELY MEASURED BY ELECTROENCEPHALOGRAPHY (EEG)

1Macquarie University, Psychology, North Ryde, Australia
2University of Newcastle, Faculty Of Health & Medicine, Callaghan, Australia
3Princess Alexandra Hospital, University of Queensland, Gastroenterology, Woolloongabba, Australia
4University of Newcastle, Callaghan, Australia
5Macquarie University Psychology, Cognitive Science, North Ryde, Australia
6Macquarie University Psychology, Psychology, North Ryde, Australia

Contact E-Mail Address: mike.jones@mq.edu.au

Introduction: Individuals suffering from functional gastrointestinal (GI) disorders have been shown to have altered central processing of visceral stimuli relative to healthy controls (1). Further such individuals appear to have selective attention to GI-related words (2) suggesting an attentional bias towards GI-relevant terms which may explain this phenomenon. They also have increased threat perception (3). However it remains unclear how much of the attention given to GI words is conscious versus unconscious. Understanding the extent to which individuals suffering from functional GI symptoms are unconsciously biased towards GI words may offer insights into therapeutic approaches to individuals in whom organic pathology has been ruled out. One previous study inferred an unconscious attentional bias for GI words through indirect means (Stroop test) (4) but its methodology was not designed to specifically measure the pre-attentional phase of central processing.

Aims and Methods: This study aimed to objectively identify differences between GI symptomatic and asymptomatic control individuals in unconscious (pre-attentional) processing of GI words using electroencephalography (EEG) which has fine temporal resolution. 26 GI symptomatic and 23 asymptomatic individuals were recruited from the community. Organic pathology and current mood disorders were ruled out by self-report. All subjects viewed 20 GI-related words, 20 negative but non-GI words and 20 neutral words from a validated word bank six times in a randomised order. Reactions were measured through ERP peak amplitude in the Occipital region in the P100 period (75-125 milliseconds) as this clearly corresponds to pre-attentional processing.

Results: Subjects generally exhibited distinctive peak amplitudes in response to all word types for the GI symptomatic subjects (p < 0.05). There was no difference in P100 peak amplitude across word type for the GI symptomatic subjects (p = 0.3). There was no difference in P100 peak amplitude for GI-relevant words between symptomatic and asymptomatic subjects (p = 0.6) nor was there an interaction between symptomatic status and word type (p = 0.8). Hence there was no suggestion of difference in P100 peak amplitude across GI-relevance of words nor symptomatic status.

Conclusion: In contrast to previous work, our data suggest that attentional bias in FGID individuals is not due to pre-attentional (unconscious) central processing and that this occurs at a later (conscious) stage. This finding has positive consequences for the development of psychological therapies targeting functional GI symptom burden since unconscious biases are much more difficult to change.

Introduction: Inflammatory Bowel Disease (IBD) increases TNF-a release from peripheral mononuclear cells as the immune system responds to inflammation in mucosal tissue. This immune response is closely linked with the intensity of gastrointestinal symptoms and extra-intestinal comorbidities such as depression or anxiety. We have previously demonstrated that anti-TNF-a treatment impacts on implicit health cognition via altering brain function (Gray et al., 2018). Increased psychiatric symptoms in IBD are commonly explained as driven by an interpretative mechanism, however there is scant direct evidence to support these interpretations. To address this mechanism, we experimentally engaged core affective circuitry and then examined the influence of anti-TNF-a therapy on brain function in patients with Crohn’s disease.

Aims and Methods: 10 patients with Crohn’s disease (age 29.3 ± 13.0 yrs, 5 female, 5 ileocolonic, 2 colonic and 3 ileal disease) on stable anti-TNF therapy (6 adalimumab, 4 infliximab) were studied twice, in randomized order, before and after anti-TNF administration. On each occasion patients underwent visceral sensory testing (standardized nutrient challenge) and then functional magnetic resonance imaging (fMRI) of the brain during an interoception task. During sensory testing 600ml of enteral feeding solution was consumed over 15 minutes while the intensity of GI symptoms was quantified. We used a recognized and commonly employed experimental protocol to recruit interoceptive neural circuits, heartbeat perception (See Brener et al., 2016 for a review of experimental methods)

Results: Within 72 hrs after administration of anti-TNF-a unpleasant visceral sensation during nutrient challenge (subjective fullness) was significantly reduced. Prior to anti-TNF-a, our experimental task robustly activated core affective circuitry including the interoceptive sensory (anterior insula) cortex and interoceptive motor (anterior cingulate) cortex. Surprisingly, activation of interoceptive circuits was not significantly altered following anti-inflammatory therapy. Instead, we observed a decrease in functional connectivity between the right anterior insula and the right amygdala was significantly reduced following anti-TNF-a.

Conclusion: Anti-TNF agents significantly reduce symptoms during a standardized nutrient challenge, and alter the strength of communication between primary sensory interoceptive cortex (anterior insula) and limbic circuitry (amygdala). Our findings are consistent with previous observations that greater amygdala functional connectivity is associated with visceral hypersensitivity (Icenhour et al., 2017). Our findings however are the first to demonstrate altered amygdala connectivity specific to interoceptive processing. These findings suggest that the functional coupling between interoceptive circuits and limbic circuits may be implicated in the translation of inflammatory conditions into psychological symptoms such as depression and anxiety. These findings support further examination of how cytokines including TNF-a may impact on mental health in gastrointestinal patients.

Introduction: Irritable bowel syndrome (IBS) is the most commonly diagnosed functional gastrointestinal disorder with a psychological distress comorbidity ranging from 15.5%–39.5%, especially with depressive disorder (DD). Twins’ studies and population genome wide association studies (GWAS) suggest there is a genetic contribution to development of IBS, rare results could display the high comorbidity rate of IBS and depression.

Aims and Methods: The aim of this study was to distinguish the genetic associations of IBS and depressive disorder. 35 diarrhea dominated IBS patients (IBS) and 35 depressive disorder patients (DD) were recruited according the Rome III criteria and MINI Diagnostic, 35 matched healthy volunteer (HC) without any gastrointestinal or mental disease were also recruited at the same time in Peking university third hospital and Beijing HuiliLongGuan Hospital. Peripheral blood DNA of each sample in the same group were extracted and mixed as a pool, the whole exome single nucleotide polymorphism (SNPs) of 3 pools were measured through the pooled-sequencing (Pool-seq)[4]. The study was approved by the Ethics Committee of Peking University Health Science Center (no. 2013-112).

Results: 10 SNPs in IBS and 12 SNPs in DD significantly different from HC and located in exonic, non synonymous and damage protein structure. 7 of them are the same: COMT rs6267, SLC7A6OS rs8063446 are the risk variants in IBS while ANKRD11 rs13527563 and MBD1 rs8063446 are the risk variants in IBS while ANKRD11 rs13527563 is the protective one. RECL4 rs4251691 is reported in Rothmund-Thomson syndrome patients. Detailed clinical data were collected from 16 patients having RECL4 mutations and diarrhea was reported in 12 out of 14 patients (6, 7). For depressive disorder patients, COMT rs6267, EDN3 rs11570255 and PPBP rs201430284 are risk variants, SCARF1 rs744644 and VASN rs3810818 show some protective effect. Gene expression (COMT) associated with experimental pain sensitivity. COMT rs6267 minor alleles in the high pain sensitive haplotype coding for 20-fold reductions in COMT enzymatic activity and correlated with schizophrenia or Parkinson’s increased risk [8, 9].

Conclusion: This is the first study using whole exome pool-sequencing to look at genetic associations of IBS and depressive disorder together in Chinese population. Our results show IBS and DD patients have the same risk mutation which are associated with neural modulation or depression. Meanwhile, specific SNPs are found in IBS or DD patients respectively. The results support that some genetic variants may lead to the high comorbidity of IBS and depression.

Introduction: Colonic diverticula are an age-dependent event in Western countries characterized by nerve fiber sprouting and neuro-immune interactions which could be involved in symptom generation.

Aims and Methods: We investigated whether stress-related mediators of the pathogenesis of IBS such as tryptase and corticosterone affect enteric glial cell (EGC) on cellular activation, cell proliferation, morphological alterations, and gene induction of neurotrophic factors and axon guidance factors. EGC (CRL-2690 purchased from ATCC) were used for the consequent experiments after recruiting to sub-confluent condition. Presence of tryptase-protoaeactivated receptor-2 (PAR-2), glucocorticoid receptor, and morphological changes of EGC was evaluated by immunofluorescence method. For EGC activation, we evaluated expressions of phosphorylated extracellular signal-regulated kinase (pERK) and nucleus factor kappa-light-chain-enhancer of activated B cells (NF-kB) by real-time RT-PCR. Expression of netrin-1 was histologically evaluated. To evaluate cell proliferation, we used the MTT assay method and cell number counting.

Results: PAR-2 was localized in the nucleus of EGC, and glucocorticoid receptor was observed in the cytoplasm of EGC. Expressions of pERK1/2 were about 2-fold higher than those of the basal control, and peaked at 2 min and 5 min after stimulation and corticosterone (1 μM) and tryptase (1 mM). Tryptase significantly increased mRNA expression levels of GFAP (1.7-fold) at 30 min and 1 hr. Regarding with morphology of EGC, corticosterone (1 μM, 6 hrs) but not tryptase remarkably caused EGC process elongation and long thin process connecting with another distant EGC. Extended cytoplasm of EGC also appeared by stimulation with corticosterone alone. Tryptase increased NGF mRNA expression at 1 hr (about 2.5-fold) and GDNF mRNA expressions at 30 min (2.9-fold) and 1 hr (3.7-fold). Then, increased NGF mRNA expression was continued until 6 hrs, but GDNF mRNA expressions were gradually decreased. While, corticosterone significantly decreased mRNA expression levels of NGF by 90% (1 μM), but increased GDNF mRNA (4-fold, 1μM) at 30 min. Netrin-1 was expressed in the EGC cytoplasm of EGC. Netrin-1 mRNA expression was increased by both stimulations (2.5-fold higher, tryptase: 1.8-fold higher, corticosterone), and its expression levels continued until 6 hr.

Conclusion: There appeared different responses of EGC between proliferation and morphology stimulated by stress mediators. Immunohistochemical responses of EGC may associate with induction of neuronal factors (NGF, GDNF, netrin-1), which possibly regulates neuronal elongation under stress conditions.

Introduction: The H. pylori management preferences and decisions of primary care physicians, or their access to different health technologies (i.e. diagnostic methods), courses and information have not generally been taken in consideration by the literature even though they currently manage most of the infections.

Aims and Methods: To evaluate the preferences, decisions and access to health technologies of Spanish Primary Care physicians. A multidisciplinary committee was involved in the design of the survey, with representatives from different regions of Spain, assessing a broad set of elements regarding preferences on management and access to health technology. Survey was submitted via e-mail to the primary care physicians, or their access to different health technologies. A strong national program is needed to ensure adequate strategies in Spain to the real access to health technology and decisions taken by the primary care physicians. Aims and Methods: Survey was submitted via e-mail to the primary care physicians. A strong national program is needed to ensure adequate strategies in Spain to the real access to health technology and decisions taken by

Conclusion: Our survey shows there is a significant deviation from recommended strategies in Spain to the real access to health technology and decisions taken by primary care physicians. A strong national program is needed to ensure adequate access to technologies and continuous medical education by primary care physicians.

Introduction: Helicobacter pylori (Hp) infection treatment is still a challenge for clinicians. Eradication rates of first-line clarithromycin-based regimens have fallen in the last 20 years, mainly due to the increase of clarithromycin resistant Hp strains. Hp culture is difficult, time consuming, not always successful and it requires an invasive procedure. 12 point mutations in the 23S rRNA gene related to clarithromycin resistance have been so far identified, in particular A2142C, A2142G, A2143G are present in 90% of cases. Aims and Methods: To evaluate the accuracy of RT-PCR performed on stool samples to detect the presence of Hp DNA while concurrently detecting point mutations in the 23S rRNA gene. Results were compared with RT-PCR carried on biopic samples. Methods: Between January and April 2018, 93 dyspeptic patients (30 males, 63 females, mean age 49.5 years) referred to our Unit to perform an upper endoscopy, were enrolled. Composite reference method (CRM): 1C urea breath test (1C UBT), rapid urease test, histology and culture were performed to establish Hp status. On Hp positive cultures, antibiogram was performed with the E-test method. On the day of endoscopy, stools specimens were collected and rapidly frozen at −20°C. Results: With the CRM method 69 patients resulted Hp positive and 24 Hp negative. In stools, 64 out of the 69 positive specimens were deemed true positive and all the negative specimens were detected properly (accuracy: 94.6%, 95% CI: 89.6% to 98.2%). Among the 23S rRNA positive samples, 30 out of 32 were deemed true sensitive and 22 out of 32 true resistant (accuracy: 81.3%, 95% CI: 69.9% to 89.9%). In biopsies, 66 out of the 69 positive specimens were deemed true positive and all the negative specimens were detected properly (accuracy: 97.8%, 95% CI: 92.4% to 99.7%). Among the 66 positive samples, 32 out of 33 were deemed true sensitive and 23 out of 33 true resistant (accuracy: 83.4%, 95% CI: 72.1% to 91.4%). PCR on stools and biopsies were highly concordant, being Cohen K coefficient 0.9 for Hp detection and 0.8 for resistance prediction. Conclusion: Helicobacter pylori DNA and 23S rRNA point mutations can be detected in human stool specimens with high accuracy, obtaining the same performance of DNA extraction from biopsies. RT-PCR on stools can therefore be used to determine the presence of the bacterium and the genotypic resistance to clarithromycin, facilitating the choice of the right therapeutic approach when endoscopy or culture can’t be performed.

Introduction: Randomized controlled trials comparing susceptibility testing guided empirical therapy for patients who fail after 2 or more eradication therapies for H. pylori are lacking.

Aims and Methods: We aimed to compare the efficacy of genotypic resistance guided therapy versus empirical therapy for eradication of refractory H. pylori infection, conducted between Oct 2012 and Sep 2017. Adult (>20 years old) patients who failed after at least 2 eradication therapies for H. pylori infection were enrolled. Eligible patients were randomized to receive either (A) genotypic resistance guided therapy for 14 days; or (B) empirical therapy according to medication history for 14 days. Eradication status was determined by 13C-urea breath test. The primary outcome was the eradication rate at least 6 weeks after eradication therapy according to intention-to-treat (ITT) analysis. Genotypic resistances of clarithromycin (23S rRNA) and levofloxacin (gyrase A) were determined by PCR with direct sequencing.

Results: Upon recruitment of 41 patients, trial 1 was terminated because of low efficacy of doxycycline sequential therapy (57.7%, 15/26). We replaced doxycycline with tetracycline in trial 2 and a total of 410 patients were randomized as the study population. Overall microbial composition as well as Shannon diversity index were determined with 16S rRNA sequencing.

Conclusion: Properly designed empirical therapy according to medication history in patients who failed more than 2 eradication therapies might improve the eradication rate.

Introduction: It was estimated that approximately 4.4 billion individuals were infected with Helicobacter pylori (H. pylori) worldwide by year 2015. As we know, H. pylori is the dominant bacterial species of gastric microbiota in H. pylori-infected patients. The domination of H. pylori can change the gastric microenvironment and result in the reconstitution of gastric microbial commnity. However, the influence of H. pylori infection on gut microbiota homeostasis is still largely unknown.

As is well known, eradication therapy of H. pylori is followed by gastric and gut microbiota alterations. Whether the alterations are beneficial or detrimental, and the effect of eradication therapy on gut microbiota were not thoroughly studied. As a typical butyric acid-producing bacterium, Clostridium butyricum (C. butyricum) has been studied in several test models and human for the eradication of H. pylori. However, most studies of C. butyricum were conducted with standard triple eradication therapy, analyzed gut microbiota alterations using bacterial culture, and emphasized the long and side effect of eradication rate and side effect. Our study analyzed the effect of C. butyricum supplementation on gut microbiota homeostasis using 16S rRNA sequencing.

Aims and Methods: Our study aimed to investigate the impact of H. pylori infection, 14-day BQ therapy and probiotic supplementation on gut microbiota homeostasis and to provide suggestions for clinical decision. A total of 70 H. pylori-positive patients and 35 H. pylori-negative patients were enrolled. Patients were randomly assigned to one of the 2 groups. In Group A, patients received 14-day BQ therapy consisting of pantoprazole, amoxicillin, furazolidone and colloidal bismuth pectin. Patients in Group B were supplemented with C. butyricum. Stool samples of H. pylori-positive patients were collected on day 0, day 14 and day 56 while stool samples of H. pylori-negative patients were collected on day 0. Gut microbiota was investigated by 16S rRNA sequencing. H. pylori status was reassessed by 13C urea breath test on day 36 for patients in group A and group B. H. pylori-negative status indicated the success of eradication treatment.

Results: 63 H. pylori-positive patients and 35 H. pylori-negative patients completed this study. Several important metabolism pathways were predicted to be more abundant in H. pylori-positive community while some human diseases pathways were with higher potential in H. pylori-negative community through KEGG pathway analysis. The abundances of most butyric acid-producing bacterium significantly decreased and those of several detrimental bacteria increased immediately after 14-day BQ therapy. The gut microenvironment homeostasis was not completely reconstituted 6 weeks after treatment in spite of a recovery tendency. Although no significant improvement of eradication rate was observed, more gastrointestinal symptoms were relieved with the supplementation of C. butyricum.

Conclusion: The role of H. pylori in human disease and gut microenvironment homeostasis may not be necessarily detrimental. The eradication of H. pylori should be based on comprehensive analysis of individual patients, especially for asymptomatic H. pylori-infected patients. The gut microbiota was extremely changed immediately after eradication therapy and 6 weeks was not enough to thoroughly reconstitute gut microenvironment balance in spite of a recovery tendency. C. butyricum might promote the recovery of gut microenvironment balance through immunological and non-immunological mechanisms.

Disclosure: Nothing to disclose
This study was supported by Eisai Co., Ltd.

The results suggested that the follow-up interval could be extended after 24 weeks in patients with clinical stage I/II (Lugano staging system) under- going H. pylori eradication therapy. The primary endpoints were complete remission (CR) rate and the rate of transfer to secondary treatment. The secondary endpoints were CR maintenance duration and overall survival (OS).

Results: H. pylori eradication therapy was successful in all 97 patients of the efficacy analysis set. CR of lymphoma was achieved in 84 of the 97 patients (86.6%), during the period of 2.0–44.7 months (median, 5.3 months) following H. pylori eradication therapy. CR was maintained in 77 of 81 patients (95.1%), who were followed for 0.4–53.2 months (median, 31.0 months). Kaplan-Meier estimates for the cumulative probability of CR maintenance were 97.5% (95% CI; 89.6–99.9%) at 12 months and 94.2% (95% CI; 85.3–97.8%) at 24 months. CR remained throughout 36 months and 48 months. Secondary treatments (radiotherapy, rituximab, or gastrectomy) for gastric MALT lymphoma were needed in 10 of the 97 patients (10.31%). During follow-up, OS rate was 96.9% (94/97). 3 patients died of causes unrelated to gastric lymphoma.

Conclusion: H. pylori eradication therapy demonstrated a high CR rate, long CR maintenance for patients with localized and H. pylori-positive gastric MALT lymphoma in this prospective, practice-based, nationwide, multicenter study. The results suggested that the follow-up interval could be extended after 24 weeks in patients with localized H. pylori-positive gastric MALT lymphoma in the patients with the same clinical characteristics enrolled in this study.

Introduction: Helicobacter pylori eradication therapy induces clinical and histological regression of gastric extranodal marginal zone B-cell lymphoma of mucosa-associated lymphoid tissue (MALT lymphoma) in the majority of cases and was approved for the first-line, standard treatment of H. pylori-positive gastric MALT lymphoma by Japanese government in 2010. Although several retrospective studies or small-scale single-centre studies have been reported, a prospective, large-scale, multi-center study has not yet been conducted in Japan.

Aims and Methods: We have conducted a prospective, nationwide, multicenter study to evaluate the clinical efficacy of rabeprazole-based triple H. pylori eradication therapy for localized H. pylori-positive gastric MALT lymphoma in practice-based clinical trial (ClinicalTrials.gov, NCT01264822). The 108 H. pylori-positive patients with clinical stage I/II (Lugano staging system) underwent H. pylori eradication therapy. The primary endpoints were complete remission (CR) rate and the rate of transfer to secondary treatment. The secondary endpoints were CR maintenance duration and overall survival (OS).

Results: H. pylori eradication therapy was successfully achieved in all 97 patients of the efficacy analysis set. CR of lymphoma was achieved in 84 of the 97 patients (86.6%), during the period of 2.0–44.7 months (median, 5.3 months) following H. pylori eradication therapy. CR was maintained in 77 of 81 patients (95.1%), who were followed for 0.4–53.2 months (median, 31.0 months). Kaplan-Meier estimates for the cumulative probability of CR maintenance were 97.5% (95% CI; 89.6–99.9%) at 12 months and 94.2% (95% CI; 85.3–97.8%) at 24 months. CR remained throughout 36 months and 48 months. Secondary treatments (radiotherapy, rituximab, or gastrectomy) for gastric MALT lymphoma were needed in 10 of the 97 patients (10.31%). During follow-up, OS rate was 96.9% (94/97). 3 patients died of causes unrelated to gastric lymphoma.

Conclusion: H. pylori eradication therapy demonstrated a high CR rate, long CR maintenance for patients with localized and H. pylori-positive gastric MALT lymphoma in this prospective, practice-based, nationwide, multicenter study. The results suggested that the follow-up interval could be extended after 24 weeks in patients with localized H. pylori-positive gastric MALT lymphoma in the patients with the same clinical characteristics enrolled in this study.

those without mucosal healing (17.56 μg/ml vs 16.10 μg/ml, p = 0.682). The AUC for VDZ levels was not different from 1-day calculation.

Conclusion: In a single-centre cohort of IBD patients, there was no association between maintenance VDZ levels and clinical remission or endoscopic mucosal healing. Shortening the dosing interval achieves higher VDZ levels, but this does not correlate with improved clinical response. This finding supports our observation that dose escalation of VDZ does not improve clinical response rates in patients with IBD. Interestingly, few patients had detectable AST despite lower rates of concomitant immunomodulator use than previously studied populations, supporting the suggestion that VDZ has lower immunogenicity than other biologics.

Introduction: In patients experiencing a loss of response to a first anti-TNF-given in monotherapy at induction or 2 months later and with an undetectable level of anti-TNF with a high level of anti-drug antibodies were included. They were randomized to receive either AZA or nothing and induction by a second anti-TNF was performed at standard doses. They were followed for 2 years after the switch, with a measurement of the clinical activity and pharmacokinetics of the second TNF at 6, 12 and 24 months. Non-primary responders after the change were excluded. A clinical failure was defined as a disease outbreak defined on a Harvey Bradshaw score >5 associated with a faecal calprotectin level >250 μg/g stool for Crohn’s disease or a Mayo score >3 with an endoscopic sub-score >1 in the case of ulcerative colitis and the need for a therapeutic change (dose intensification, change in treatment, addition of corticosteroids or AZA, use of surgery). The appearance of unfavorable phenotype was defined by the appearance of low or undetectable levels of anti-TNF with anti-drug antibodies.

Results: 90 patients (48 CD, mean age: 39.5 years, sex ratio M/W: 0.95) were included. The second anti-TNF was adalimumab (ADA) and infliximab (IFX) in 40 and 50 patients, respectively. 4 patients were of the AZA phenotype (B3) (IFX, n=1; ADA, n=1; IFX, n=1; ADA, n=1), 48.4% were women. There were 148 patients with CD and 36 with UC. 86 patients were treated with IFX (n=86, REM or CT-P13) and 98 with ADA. Median disease duration was 3.69 (IQR: 10.37) years. In CD, median Harvey-Bradshaw index was 6.27 had a penetrating phenotype (B3) (IFX, n=17; ADA, n=10) and 23 had perianal fistulas (IFX, n=18 ADA, n=6). In UC, median Mayo subscore was 6.19. 16% had extra-intestinal manifestations. Concomitant immunosuppressors were prescribed in 68% and 40% of patients treated with IFX and ADA respectively. 82% and 35% of patients treated with IFX and ADA received corticosteroids, respectively. At 1 year, 95 patients (51.6%) were in clinical remission, including 73 (40%) without optimization of anti-TNF therapy. ADA were detected in 51 patients (27.7%). The immunogenicity rate for ADA and IFX was 38.8% and 15.1%, respectively. Mean time to onset of ADA was 2.5 months, and ADA persisted over time in 72%. Drug levels at 6 weeks of therapy were significantly lower in patients who developed ADA. Immunogenicity was associated with non-remission at 1 year (58.6% in patients with ADA vs 35.7% in patients without ADA, p = 0.008). In multivariate cox regression analysis of time to ADA development, immunogenicity was associated with concomitant immunosuppressors (HR: 0.39 [95% CI 0.2–0.75]), anti-TNF levels at 6 weeks of therapy (HR: 0.86 [95% CI 0.7–0.91]), antibiotics usage during the study (HR: 0.9 [95% CI 0.14–0.65]) and vaccine in the year before start of anti-TNF therapy (HR: 5.32 [95% CI 1.5–16.3]).

Conclusion: In IBD patients, immunogenicity towards anti-TNFs is associated with a lower remission rate and lower drug levels. Concomitant immunosuppressors and antibiotics are associated with a lower risk of immunogenicity while vaccine received before the start of anti-TNF are associated with an increased risk of immunogenicity.

Introduction: Magnetic resonance enterography (MREn) may be used in clinical practice to assess disease activity in Crohn’s disease (CD).1-2 Vedolizumab (VDZ) is clinically effective in patients (pts) with moderately to severely active CD, but healing with VDZ on MREn has not been previously measured. This study evaluated the effect of VDZ on radiologic remission using MREn at weeks (wks) 26 and 52 in pts with active CD.

Aims and Methods: VERSIFY (NCT02425111) was a Phase 3b, open-label study evaluating endoscopic remission with VDZ in 101 pts at wk 26 and in 56 eligible pts at wk 52 following a protocol amendment extending treatment duration. Only patients receiving VDZ at the time of the amendment, or enrolled after the amendment were eligible to be treated to wk 52. Pts were enrolled with moderate-severe CD (CD Activity Index 220±40; Simple Endoscopic Score for CD ≥7; ≥1 mucosal ulceration on centrally read endoscopy) and who had prior failure to a corticosteroid, immunomodulator, and/or ≥1 TNF antagonist (tumour necrosis factor inhibitor). The MREn substudy enrolled 37 pts of whom 21 were eligible to continue treatment to wk 52. The exploratory endpoint was Magnetic Resonance Index of Activity (MaRIA) score,4 quantified in 6 ileocolonic segments (1 ileal and 5 colonic). MaRIA-7 remission of all active lesions and MaRIA-11 remission of only severe lesions were defined as scores of <7 and <11, respectively, in all segments, and were assessed at wk 26 and wk 52. Data were analysed in the full analysis set (FAS; all treated pts) and in the per-protocol set (PPS; treated pts with sufficient data at baseline and post-baseline). Only pts with an abnormal MaRIA score of ≥7 or ≥11, respectively, in all segments, were included in the analysis. If no relevant post-baseline MaRIA scores were available then they were considered non-responders in the FAS. Subgroup analyses of the FAS and PPS by prior TNF exposure were performed.

Results: Of 37 pts enrolled into the MREn substudy, 32 pts had a baseline MaRIA score ≥7 in ≥1 segment and 32 had a baseline score ≥11 in ≥1 segment. These pts were included in the MaRIA-7 and MaRIA-11 remission analysis. The 5 pts who did not meet the threshold for inclusion in the MaRIA-7 remission analysis were classified as having ‘suboptimal’ MREn exams at baseline. 27/32 pts had 26 wk observations. 15/21 MREn pts had 52 wk observations. At baseline, were classified as having ‘suboptimal’ MREn exams at baseline. 27/32 pts who did not meet the threshold for inclusion in the MaRIA-7 remission analysis. These pts were included in the MaRIA-7 and MaRIA-11 remission analysis. The MaRIA-7 score was quantified in 6 ileocolonic segments (1 ileal and 5 colonic). MaRIA-7 and MaRIA-11 remission at wk 26 and wk 52.

Conclusion: VDZ can induce radiologic remission (MaRIA-7) in a difficult-to-treat population with moderately to severely active CD, both in those naive to, or who had failed, anti-TNF therapy.

Introduction: Vedolizumab (VDZ), a humanized monoclonal antibody targeting α4β7 integrin, is effective in induction and maintenance therapy in patients with inflammatory bowel disease (IBD) who have not adequately responded to standard therapies, and high levels of vedolizumab trough levels (VTL) have been associated with clinical remission. The α4β7 integrin binds to endothelial MadCAM-1 and is up-regulated by retinoic acid (RA).

Aims and Methods: To determine the relations between soluble MadCAM-1 (sMadCAM-1) and RA concentrations with clinical remission during VDZ maintenance therapy. In a retrospective study performed in IBD patients treated with VDZ, we measured VTL, sMadCAM-1 and RA concentrations.

Results: Among the 62 included patients (38 Crohn’s disease) 24 relapsed and 38 stayed in remission between weeks 10 to 30 after VDZ initiation. During this maintenance therapy, median values of VTL and RA were 15.4 μg/mL and 0.97 ng/mL, whereas sMadCAM-1 was undetectable (<0.41 ng/mL) in 67.3%
of samples. The positive predictive value (PPV) of undetectable sMACAM-1 for clinical recurrence was 80%, with a corresponding sensitivity of 74.6%. On multivariate analysis undetectable sMACAM-1 and high VTL (> 19 mg/L) were independently associated with clinical recurrence (OR = 7.5, p = 0.006 and OR = 2.2, p = 0.045, respectively). The combination of sMACAM-1 < 0.41 mg/L and VTL > 19 mg/L was the best pharmacokinetic profile with an AUC of 95.2%. Median values of sMACAM-1 and RA were significantly higher (p = 0.0001) before VDZ therapy than during the follow-up (sMACAM-1: 40.5 vs. < 0.41 mg/L; RA: 1.7 vs. 0.97 mg/L). Only RA > 1.60 mg/L before VDZ therapy was predictive of clinical recurrence during the follow-up (AUROC = 80.7%).

Conclusion: Undetectable sMACAM-1 appears strongly associated with clinical recurrence during VDZ maintenance therapy. Combination of undetectable sMACAM-1 with high VTL is also potentially interesting for therapeutic drug monitoring. Baseline RA concentrations are predictive of clinical remission. These findings need to be confirmed in further prospective studies.

Disclosure: Nothing to disclose.
from chronic active ulcerative colitis received repeated fecal microbiota trans-
plantation (FMT) according to the standard protocol, using donor stool pre-
paration. 25 patients (mean age 36 ± 15) were treated with frozen donor stool (mixed with sodium chloride and glycerol, stored at -80 °C), 24 patients (mean age 44 ± 9) with freshly prepared donor stool (not older than 6 hours). Response and remission were determined by the total Mayo score (TMS) before FMT and after 90 days. Clinical response was defined as a decrease of ≥3 points in TMS from baseline, along with either a decrease of ≥1 point in the rectal bleeding subscore or the absolute rectal bleeding subscore of 0 or 1. Remission was defined as a TMS < 2 and an endoscopic subscore of 0 or 1.

Results: The mean TMS was 9.2 ± 2.2 (frozen stool) and 9.9 ± 1.8 (fresh stool) at baseline and was reduced to 5.1 ± 2.7 in the frozen donor stool group and to 5.3 ± 3.6 in the fresh donor stool group at day 90. The mean improvement in TMS between baseline and day 90 was statistically not significant different between the two groups (p = 0.691). Furthermore, remission and response rates were comparable between frozen donor stool and fresh donor stool cohorts (No response/Response/Remission: 40%/40%/20% vs. 42%/33%/25%; p = 1.00/ 0.769/0.742).

Conclusion: In chronic active ulcerative colitis frozen donor stool for FMT is as effective as fresh donor stool in inducing response and remission in ulcerative colitis. By using frozen donor stool FMT may become more available for the clinical use in this patient group.

OP181 RANDOMISED CLINICAL TRIAL: SINGLE INFUSION-VERSUS MULTIPLE INFUSION FAECAL MICROBIOTA TRANSPLANTATION FOR THE TREATMENT OF SEVERE CLOSTRIDIUM DIFFICILE INFECTION REFRACTORY TO ANTIBIOTICS

1IRCCS Fondazione Agostino Gemelli University Hospital, Digestive Disease Center, Rome, Italy
2IRCCS Fondazione Agostino Gemelli University Hospital, Microbiology Institute, Rome, Italy

Contact E-Mail Address: gianluca.ianro@hotmail.it

Introduction: Faecal microbiota transplantation (FMT) is a highly effective treatment against recurrent C. difficile infection. Far less evidence exists on the efficacy of FMT in treating severe C. difficile infection refractory to antibiotics.

Subjects with severe C. difficile infection refractory to antibiotics were randomly assigned to 1 of the 2 following treatment arms: 1) FMT-S, including a single faecal infusion via colonoscopy followed by a 14-day vancomycin course; 2) FMT-M, including multiple faecal infusions plus a 14-day vancomycin course. In the FMT-M group, all patients received at least 2 infusions, while with pseudomembranous colitis (PMC) underwent further infusions until the disappearance of pseudomembranes. The primary outcome was the cure of refractory C. difficile infection.

Results: 36 subjects, 2 in each treatment arm, were enrolled. 21 patients in the FMT-S group and 28 patients in the FMT-M group were cured, respectively (75% versus 100%, respectively, both in PP and ITT analyses; p = 0.01). No serious AEs were associated with any of the 2 treatment protocols. However, a pseudomembranous-associated single-shot FMT protocol in curing severe C. difficile infection refractory to antibiotics.

Contact E-Mail Address: khanna.sahil@mayo.edu

Introduction: To broaden access to microbiota-based therapeutics therapies, RBX7455, a non-frozen, lyophilized, orally-administered microbiota-restoring therapy candidate was developed. We report interim results from an open-label Phase 1 trial of RBX7455 for preventing recurrent C. difficile infections (rCDI).

Aims and Methods: 25 patients with ≥2 CDI episodes following ≥2 courses of antibiotic therapy have been enrolled to date in 3 cohorts as follows: 1) 4 RBX7455 capsules twice daily for 4 days, n = 10; 2) 4 RBX7455 capsules twice daily for 2 days, n = 10; 3) 2 RBX7455 capsules twice daily for 2 days, n = 5. Success was defined as absence of CDI recurrence through 8 weeks after treatment completion, and adverse events were monitored during and after treatment.

Results: 9 of 10 patients in cohort 1, 8 of 10 patients in cohort 2, and 5 of 5 patients in cohort 3 were recurrence-free at the 8-week endpoint, with an overall success rate of 88% (22/25). A total of 37 non-serious adverse events (AEs) have been recorded to date, with gastrointestinal AEs being most common. No serious AEs have been observed.

Prior to treatment, the taxonomic compositions of responder microbiomes were significantly dissimilar from the RBX7455 composition and were dominated by Gammaproteobacteria and Bacilli. After treatment, patient microbiomes converged toward the RBX7455 composition, with Bacteroidia and Clostridia becoming more predominant. Microbiome changes were similar among responders from all cohorts.

Conclusion: 3 different dosing regimens of RBX7455 had a high success rate in preventing rCDI with no serious AEs. In addition, RBX7455 appears to restore patient microbiomes toward the RBX7455 composition. Microbiome and safety data collection will continue for 6 months after treatment.

OP183 TREATMENT OF GASTRIC FUNDAL VARICES WITH EUS-GUIDED EMBOLISATION COMBINING COIL PLACEMENT WITH THROMBIN INJECTION

C. Shekhar1, 2, I. Ororukwe1, D. Tripathi1, C. Forde1, B.S. Mahon1

2Manor Hospital, Gastroenterology, Walsall, United Kingdom

Contact E-Mail Address: drcshekhar@gmail.com

Introduction: Gastric varices are present in 5-33% of patients with portal hypertension with incidence of bleeding of around 25% in 2 years1. If gastric varices are the source of bleeding, therapeutic options include endoscopic therapies, TIPSS, surgery and non-selective beta-blockade2. There are reports of EUS-guided coiling combined with cyanoacrylate glue3 but limited literature on safety and efficacy of EUS-guided coil embolisation with human thrombin injection. We report our experience.

Aims and Methods: We analysed data of all EUS-guided interventions for the management of bleeding gastric varices between 2015-2017 at a liver transplant center. Olympus EUS linear scope was used to inject human thrombin (Tissose®; 500U/ML) in gastric varices with or without coils (Nester® Embolisation Coils).

Results: A total of 10 EUS-guided interventions in 6 patients (4M & 2F), aged 55 (41-59) yrs for secondary prophylaxis. 67% had cirrhosis with MELD score of 14 (10-21) and 75% were Child-Pugh class C. The remainder had non-cirrhotic portal hypertension. All patients had previous bleeding from gastric varices and 2/3rd were intolerant of beta-blockers. 67% had previous thrombin injection that had failed to obliterate the gastric varices. EUS-guided coil embolisation was performed in 6 patients (2 had thrombin injection in situ, and thrombolytic agent that had failed previous coiling embolisation). The largest feeding vessel was 120 (7-16) mm with a median 5 (2-10) coils placement followed by thrombin injection of 3500 (2500-5000) IU.

Most (8/10) stayed overnight after intervention and only 2 required longer stays, Median F U was 9 (3-20) months with zero 30-day mortality. 1 patient had fever 2 days post procedure requiring IV antibiotics. No reported episodes of re-bleeding except in 1 patient at 23 months. 4 had follow up EUS (5-7 months) and showed no flow at the level of the coils. 1 patient died within 3 months of procedure secondary to hepatic decompensation.

Conclusion: In our experience EUS-guided coil embolisation and injection of thrombin is a technically safe and well-tolerated procedure even in patients with significant comorbidities especially who have failed eradication of gastric varices from single modality therapy. Due to the lower incidence of gastric variceal bleeding in comparison to oesophageal varices bleeding, we recommend multi-center prospective data collection evaluating the modalities being used and reporting of outcome data to help inform national guidelines.

Disclosure: Nothing to disclose

References
1. Garcia-Tsao G, Abraldes J, Berzigotti A, Bosch J. (2017) Treatment of esophageal varices in one of the dreadful complications of portal hypertension [1]. Upper endoscopy is the gold standard for diagnosing esophageal varices [2]. Noninvasive methods were applied in order to predict the presence of esophageal varices and their response to medical treatment [3]. One method is the splenic stiffness measurement [4]. Many studies were carried out for evaluating this technique, all of them agreed on the benefit, however, their results were different regarding a specific unified cut-off value and the capability of identifying the size of the varices [5]. These differences were thought to be due to readings exceeding the maximum value (75 kPa) of the machine [6].

Carvedilol is a nonselective b-blocker used to reduce portal pressure in order to prevent variceal bleeding [7], being a potent therapeutic agent with dual action (non-selective b-blocker and adrenoergic blocker) [8]. Effective dose of carvedilol for reducing portal pressure with the least arterial hypotension was found to be 12.5mg d-1 [9].

Aims and Methods: The aim of this study is to investigate the possibility of using the spleen stiffness measurement by transient elastography as a noninvasive approach to detect esophageal varices, and comparing the results obtained to liver stiffness measurement and platelet count to spleen diameter ratio in detecting and grading the size of varices. The study also aims to monitor changes in spleen stiffness before and after carvedilol therapy.

This was a single-center, prospective cross-sectional study, conducted on 110 individuals (90 chronic HCV patients and 20 healthy controls). Patients were divided into 4 groups: Group 1: Healthy controls, Group 2: Chronic Hepatitis, Group 3: Cirrhosis without varices, Group 4: Cirrhosis with varices.

All patients enrolled were over 18 years of age. Patients with transient elastography technical difficulty, contraindication to b-blockers, pregnant females, thrombocytopenia, portal hypertension requiring medications, and those undergone previous endoscopic management of esophageal varices were excluded from the beginning. Each patient underwent abdominal ultrasound and laboratory investigations, cirrhotic patients (60) were furtherly subjected to doppler ultrasonography to confirm portal hypertension, then upper endoscopy to verify the presence of esophageal varices, patients with esophageal varices were prescribed carvedilol (6.25mg twice daily) (30). Liver and spleen stiffness was done for all patients once and it was repeated again for patients who received carvedilol after three month of treatment as described.

Results: There was statistical significant difference between all groups in terms of both liver and spleen stiffness (p < 0.001). An inverse correlation was found in group 4 between spleen stiffness before treatment and the spleen size (R-value = 0.438, p = 0.016). Patients in group 4 showed a statistical significant difference in spleen stiffness measurement before and after treatment (p < 0.001). Spleen stiffness measurement was capable of predicting the presence of esophageal varices at cut off 59.85 kPa with AUC 0.768, showing sensitivity 80% and specificity 70%.

Conclusion: Spleen stiffness measurement by transient elastography is a reliable noninvasive method in predicting the presence of esophageal varices compared to other noninvasive methods and monitoring of treatment by carvedilol; however, it was not capable of identifying the size nor the risk of variceal bleeding.

2-year survival rates of 69.6% and 86.3%, respectively. There was no difference in survival with estimated 1-year survival rates for C. Shekhar

**Introduction:** Gastric variceal bleeding is less common than esophageal variceal bleeding; however, it is associated with a high morbidity and mortality rate. The aim of our study was to compare the balloon-occluded retrograde transvenous obliteration (BROTO) with cyanoacrylate injection for the prophylaxis of recurrent gastric variceal bleeding.

**Aims and Methods:** Between June 2015 and June 2018, 64 patients with variceal bleeding were assigned either balloon-occluded retrograde transvenous obliteration (n = 32) or cyanoacrylate injection (n = 32). The mean duration of follow-up period was 415 ± 250 days in the BROTO group and 404 ± 210 days in the cyanoacrylate group. Foam sclerotherapy using lauromacrogol by BROTO was performed.

**Results:** The technical success rate was 100% (32/32 patients) in the BROTO group. The amount of lauromacrogol used was 12.5 ± 4.5 ml (range, 3-20 ml). Significant rebleeding occurred in 1 patient (21.9%) of the BROTO group, and 7 patients (21.9%) of cyanoacrylate injection group (p = 0.023). The cumulative probability of remaining free of all-cause rebleeding was significantly higher in the BROTO group than in the cyanoacrylate group; the probability at 1 year was 88.9% in the BROTO group and 78.1% in the cyanoacrylate group (p = 0.024). There was no difference in survival with estimated 1-year survival rates for BROTO and cyanoacrylate injection treated patients of 90.5% and 86.3%, and 2-year survival rates of 69.6% and 83.6%, respectively.

**Conclusion:** These results suggest that the BROTO is more effective than cyanoacrylate injection in prevention of gastric variceal rebleeding. Survival is similar in the 2 groups.

Introduction: Primary sclerosing cholangitis (PSC) is a chronic, progressive struc-
turing disease of bile ducts that may eventually lead to cirrhosis and cholangio-
carcinoma (CCA). The etiopathogenesis is heterogeneous, involving both genetic and
environmental factors. Early diagnosis and better tools for monitoring pro-
gression of PSC and detection of biliary dysplasia is a major medical challenge. Novel biomarkers enabling a more precise diagnostic and prognostic markers of both PSC and biliary dysplasia are urgently needed.

Aims and Methods: This study aimed identifying a set of lipids in bile that would
serve as biomarkers for detection and prognosis of PSC and biliary dysplasia.
After informed consent, bile samples (n = 131) were drawn from participants
(n = 147) distributed across 4 experimental groups: non-advanced PSC (n = 63),
advanced PSC with biliary dysplasia (n = 24), and healthy controls (n = 60).
The samples were subsequently analyzed using a novel lipid-screening platform
(LipidyzerTM, Sciex) to determine the concentration of 1134 lipids species across 13 lipid classes.

Results: Model based analyses (Generalized Estimating Equations) pinpointed the following set of lipids as altered in PSC patients with respect to healthy controls, after correcting for type-I error: lysophosphatidylcholines (LPC(18:3),
LPC(20:4), LPC(20:5), and LPC(22:5),; lowest p = 0.4610^-3), lysophosphatidyl-
ethanolamines (LPE(20:3)); lowest p = 0.3060^-3), sphingomyelins (SM(14:0/16:1),
SM(14:0/18:1), SM(16:0/18:1), SM(18:0/18:1), and SM(18:0/18:2),; lowest p = 0.2371^-3),
phosphatidylethanolamines (total PE, PE(16:0/16:1), PE(16:0/18:1), PE(16:0/18:2), PE(16:0/18:3), PE(16:0/20:4),
PE(18:0/18:1), PE(18:0/18:2), PE(18:0/18:3); total PC, PC(14:0/16:1), PC(16:0/18:1), PC(17:0/18:1),
PC(17:0/20:4), PC(18:0/18:1), and PC(18:0/18:3); lowest p = 0.3271^-3),
phosphatidylserines (PS, PS(14:0/16:1), PS(14:0/18:1), PS(16:0/18:1),
PS(16:0/20:4), and PS(18:0/20:4); lowest p = 0.3271^-3), and complex lipids (fatty
acids, triglycerides, cholesterol esters, and sterol esters) (lowest p = 0.3271^-3),
respectively, and PE (hexadecanoyl PE, heptadecanoyl PE, oleic PE,)
acidic PE, eicosanoyl acid, eicosapentaenoic acid; lowest p = 0.4610^-3),
PE (eicosanoyl acid; p = 0.3271^-3), PC (16:0/16:1), PE(16:0/18:1) and
PC(18:0/18:2); lowest p = 1.8510^-3).

Conclusion: From the extensive lipid panel initially screened, this study was cap-
able of detecting a set of 34 candidate bile biomarkers that allowed differentiating between persons affected with PSC and biliary dysplasia from the healthy controls.

Contact E-Mail Address: s.haal@amc.uva.nl

Introduction: The cornerstone of treatment in cholangitis is successful drainage of the biliary tract by means of an ERCP in combination with antibiotics. Recommendations in current international guidelines regarding the duration of antibiotic treatment after adequate drainage vary from 3 days or less up to 10 days. The Dutch (SWAB) guideline recommends antibiotics for 3 days or less. However, high level of evidence to justify this recommendation is lacking. Our aim was to assess the incidence of infectious complications after adequate drainage of ascending cholangitis and to evaluate the potential influence of the antibiotic duration.

Aims and Methods: We performed a retrospective multicenter study in 7 medical centers in the Amsterdam region. Patients with cholangitis due to choledocholithiasis between January 2012 and January 2017 were extracted from local pro-
spective endoscopy databases. Adequate drainage by means of ERCP was required. The primary outcome was number of infectious complications within 3 months after the initial ERCP. An infectious complication was defined as the need for antibiotics within 3 months after ERCP. Secondary outcomes included development of hospital stay and infection.

Results: 427 patients were identified (disease between 1972 and 2018); 321/472 (68%) male, median age at diagnosis 51 (11-92) years. The null model showed evidence of disease clustering with areas of high and low disease prevalence (controlled for population size). The areas of highest risk were in rural Cumbria (RR 1.755) and lowest risk in urban Durham and Teeside (RR 0.6243).
Models using single spatial covariates: urban-ness, traffic, landfill sites, coal mines, lead mines, sandstone quarries, limestone quarries, Townsend score (a measure of social deprivation) and water hardness (concentration of calcium, magnesium, iron, silicon, pH) and a multi-covariate model containing covariates showed to be significant at 95% Bayesian Credibility Intervals (BCIs). Deviance Information Criterion (DIC) was used to compare the fits of models. All models were performed after controlling for the area size of each postcode district. There were 3 main questions:
1. Is the prevalence of PSC in a defined area greater than that expected by chance i.e. disease clustering?
2. If so, is elevated risk associated with any environmental risk factors local to the case?
3. If elevated risk dependent on socio-economic status?

Results: 472 patients were identified (disease between 1972 and 2018); 321/472 (68%) male, median age at diagnosis 51 (11-92) years. The null model showed evidence of disease clustering with areas of high and low disease prevalence (controlled for population size). The areas of highest risk were in rural Cumbria (RR 1.755) and lowest risk in urban Darlington and Teeside (RR 0.6243).
Models using single spatial covariates showed that only urban-ness and Townsend score significantly improved the null model with 2.5% and 95% confidence intervals not crossing 0. A multi-covariate model (combining urban-ness and Townsend score) did not improve the model further. There was a statistically significant difference in the Townsend scores of the 20 patients living in areas of highest and lowest prevalence (p < 0.0001) with lower Townsend scores (i.e. less social deprivation) seen in areas of high disease prevalence.

Conclusion: A higher prevalence of PSC was seen in more rural, less deprived areas. This inverse association with social deprivation is the opposite to that seen in other geographical studies of many other diseases, including liver disease, and warrants further investigation into potential disease triggers. The association between rurality raises the possibility of an association with processes in these areas e.g. farming, pesticide use.

Introduction: Obeticholic Acid (OCA) is a selective and potent farnesoid X receptor agonist indicated for treatment of primary biliary cholangitis (PBC). POISE is a 12-month double-blind (DB), placebo (PBO)-controlled, Phase 3 PBC study including an open-label extension (OLE).

Aims and Methods: The purpose of the OLE is to assess safety and durability of the OCA effect on serum markers of cholestasis. Key POISE inclusion criteria: PBC diagnosis, ALP ≥ 1.67x ULN and/or total bilirubin (TB) > ULN to < 2x ULN, stable UDCA dose or unable to tolerate UDCA. During the DB phase, pruritus was the most common side effect of OCA, but discontinuation due to pruritus continues to be infrequent.

Results: 193 of 198 (97%) patients completing the DB phase of the study enrolled in the OLE: 165 reached 36 months of the OLE. PBO, n = 49; OCA 5-10 mg, n = 59; OCA 10 mg, n = 57. At the end of the DB phase, patients on OCA had significant reductions in ALP and patients on PBO did not (Table 1). ALP reduction observed in OCA-treated patients was durable through 36 months OLE. PBO-treated patients experienced a significant reduction in ALP after switching to OCA, which was durable through 36 months OLE. Similar durable improvements were seen for GGT, ALT, and AST (data not shown). For OCA-treated patients, mean TB remained below BL through 36 months OLE. For PBO-treated patients, mean TB increased at 12 months DB, but trended back toward baseline (BL) with 36 months of OCA during OLE. During the OLE, 28 (15%) patients discontinued treatment, 7 (4%) patients for pruritus.

Conclusion: OCA treatment results in improvement in liver biochemistry; this improvement is durable in this analysis. For patients initially treated with PBO, switching to OCA is also associated with a durable biochemical response. Consistent with the DB phase, pruritus was the most common side effect of OCA, but discontinuation due to pruritus continues to be infrequent.

DB Phase Treatment Group PBO OCA 5-10 mg OCA 10 mg

Introduction: Janus Kinase (JAK) inhibitors are emerging as a promising treatment option for ulcerative colitis (UC). The efficacy and safety of upadacitinib (UPA), a JAK1-selective inhibitor, was assessed in an 8-week double-blind placebo (PBO)-controlled dose-ranging Phase 2b induction study in patients (pts) with moderately-to-severely active UC who had inadequate response, loss of response or intolerance to corticosteroids (CS), immunosuppressants (IS), or biologic therapies.

Aims and Methods: Adult pts with moderately-to-severely active UC (Adapted Mayo Score [Mayo score without Physician Global Assessment] 5-9 points and centrally-read endoscopic subscore ≥2-3) were randomized to receive extended-release UPA 7.5, 15, 30, 45 mg once daily (QD) or PBO for 8 weeks. Pts were stratified by previous biologic use, baseline (BL) CS use, and BL Adapted Mayo score (≤5). A dose-response relationship between UPA doses and PBO for the primary endpoint, clinical remission per Adapted Mayo Score at week 8 (defined as stool frequency subscore [SFS]≤1, rectal bleeding subscore [RBS] = 0, endoscopic subscore [ES]≤1), was tested by Multiple Comparison Procedures Modeling (MCP-Mod) using pre-specified candidate models in the intent-to-treat population. Pairwise comparisons between UPA doses and PBO for the primary and ranked secondary endpoints were also conducted using the Cochran-Mantel-Haenszel test stratified by randomization factors. Non-responder and last observation carried forward imputations were utilized for missing data.

Introduction: Many patients with Crohn’s disease (CD) report that the use of medical cannabis improves their symptoms, however studies evaluating objective disease parameters including inflammatory markers and endoscopic score are lacking.

Aims and Methods: To assess the effect of cannabis treatment on Crohn’s disease patients.

Methods: In a double blind, randomized, placebo-controlled trial on CD patients with active disease Patients were randomized to receive either cannabis oil with 15% Cannabidiol (CBD) and 4% tetrahydrocannabinol (THC) or placebo for 8 weeks. All other medications remained unchanged. Disease-related outcome measures including Crohn’s disease activity index (CDAI), C-reactive protein (CRP), fecal calprotectin, simple endoscopic score for Crohn’s disease (SES-CD) and SF-36 quality of life (QOL) were assessed before, during and after treatment.

Results: A total of 46 patients, 31 males (67%), mean age ± 35±12, were investigated. Each study group included 23 patients. CDAI before the treatment was 288.4 ± 78.0 and 298.5 ± 112.2 (p = 0.71), after 8 weeks of treatment the CDAI was 143.1 ± 96.0 and 209.5 ± 131.0 in the cannabis and placebo groups, respectively (p = 0.05). Remission rate (defined as CDAI < 150) was achieved in 65% (29/46) and 55.6% (25/45) of patients, respectively (p = 0.40). The potential anti-inflammatory properties of cannabis treatment in IBD/Crohn’s disease requires further investigation.

Disclosure: Bar-Lev Schleider Lhi is an employee of Tikun Olam, a supplier of medical cannabis.

OP197 TOFACITINIB IS MILLIGRAMS TWICE DAILY FOR PATIENTS WITH MILD TO SEVERE ULCERATIVE COLITIS: RESULTS FROM 8-WEEK INDUCTION STUDIES OCTAVE INDUCTION 1 & 2

Introduction: Tofacitinib is an oral, small molecule Janus kinase inhibitor that is being investigated for ulcerative colitis (UC). The efficacy and safety of tofacitinib in patients with ulcerative colitis disease severity score (UCDSS) C10 were previously reported in a 2-week, Phase II study (NCT01465763 & NCT01465764). The current study trial protocols called for patients to be randomised to either tofacitinib 10 or 15 mg BID or placebo. The primary endpoint of interest was the proportion of patients achieving a primary clinical response (PCI) at Week 8.

Results: 77 patients (44 males, 33 females) with an average age of 38.3 years and a disease duration of 8.2 (2.5) years. At BL, 77.6% had prior use of biological modulators or tumour necrosis factor inhibitors. Remission (total Mayo score <2, no subscore >1 and rectal bleeding subscore of 0), mucosal healing (Mayo endoscopic subscore ≤1) and clinical response (decrease from baseline total Mayo score of ≥3 points and ≥30%, plus decrease in rectal bleeding subscore ≥1 or absolute subscore ≤1) were evaluated based on central reading of endoscopic subscore. Differences from placebo and 95% confidence intervals (CI) were calculated using an exact method.

Aims and Methods: We report pooled efficacy and safety analyses from OCTAVE Induction 1 & 2 for the tofacitinib 15 mg BID dose alongside data from the tofacitinib 10 mg BID groups previously reported. Patients were ≥18 years of age and had failed, or were intolerant to, corticosteroids, immunomodulators or tumour necrosis factor inhibitors. Remission (total Mayo score ≤2, no subscore >1 and rectal bleeding subscore of 0), mucosal healing (Mayo endoscopic subscore ≤1) and clinical response (decrease from baseline total Mayo score of ≥3 points and ≥30%, plus decrease in rectal bleeding subscore ≥1 or absolute subscore ≤1) were evaluated based on central reading of endoscopic subscore. Differences from placebo and 95% confidence intervals (CI) were calculated using an exact method.

Results: Baseline demographics and disease characteristics of the 22 patients who received tofacitinib 15 mg BID during OCTAVE Induction 1 & 2 were generally consistent with the overall study population. At Week 8 in the tofacitinib 15 mg BID group, the primary efficacy point of remission was achieved by 9 (40.9%) patients, mucosal healing by 13 (59.1%) patients, and clinical response by 19 patients (86.4%). Treatment effect sizes (ie difference from placebo [95% CI]) were 34.9% (15.6, 54.6) for remission, 45.4% (23.5, 65.3) for mucosal healing (Mayo endoscopic subscore ≤1) and clinical response (decrease from baseline total Mayo score of ≥3 points and ≥30%, plus decrease in rectal bleeding subscore ≥1 or absolute subscore ≤1) were evaluated based on central reading of endoscopic subscore. Differences from placebo and 95% confidence intervals (CI) were calculated using an exact method.

Disclosure: The authors declare that they have no conflicts of interest.

Results: 18 patients (9 males, 9 females) with an average age of 38.3 years and a disease duration of 8.2 (2.5) years. At BL, 77.6% had prior use of biological modulators or tumour necrosis factor inhibitors. Remission (total Mayo score ≤2, no subscore >1 and rectal bleeding subscore of 0), mucosal healing (Mayo endoscopic subscore ≤1) and clinical response (decrease from baseline total Mayo score of ≥3 points and ≥30%, plus decrease in rectal bleeding subscore ≥1 or absolute subscore ≤1) were evaluated based on central reading of endoscopic subscore. Differences from placebo and 95% confidence intervals (CI) were calculated using an exact method.

**OP198 EFFICACY AND SAFETY OF GASTRO-RESISTANT PHOSPHATIDYLCHOLINE (LT-02) FOR INDUCTION OF REMISSION IN PATIENTS WITH MILD-TO-MODERATE ULCERATIVE COLITIS REFRACTORY TO MESALAZINE: A RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY (PCG-2)**

**Introduction:** An observed deficiency of phosphatidylcholine (PC) in the intestinal mucus in patients with ulcerative colitis (UC) [1] led to the hypothesis that daily oral administration and subsequent gastro-resistant release of PC into the ileum could restore the protective mucus barrier function.

**Aims and Methods:** This was a prospective, double-blind, randomised, multicentre phase 3 trial to compare the efficacy and safety of 2 different dosing regimen of LT-02 (LT-02 0.8 g QID, LT-02 1.6 g BID) with placebo over 12 weeks for induction of remission in patients with active ulcerative colitis (mDAI score 4-10, <10% 1 point in each of the four subscores) refractory to mesalazine despite either continued treatment with oral 5-ASA ≥ 2.4 g/d or ≥ 6 weeks or combination of oral 5-ASA ≥ 2.4 g/d and a rectal 5-ASA preparation for ≥10-14 days. Subjects had to have fecal calprotectin (FCP) ≥ 250 μg/g at screening or FCP ≥ 100 μg/g and Histological Index (HI) ≥ 1. Primary endpoint was the percentage of patients in deep remission defined as mDAI Score ≤ 1 with a score of 0 points for rectal bleeding and stool frequency, and ≥ 1 point reduction from baseline in the mucosal appearance score. After a pre-specified interim-analysis, the study was stopped for futility.

**Results:** The full analysis set (FAS) comprised 465 patients. Both the primary and the secondary efficacy endpoints did not show significant differences across treatment groups.

Introduction: Vedolizumab (VDZ), a humanized monoclonal antibody inhibiting α4β7 integrin, is approved globally for the treatment of ulcerative colitis (UC). However, data on its safety and efficacy is limited in the Asian population. We conducted a phase 3, randomized, double-blind, placebo (PBO)-controlled study in Japanese patients (pts) with UC (NCT02039505), where 1 of 2 primary end-points was remission clinical response at Week 10 (induction phase, IP) was numerically greater but not significant, and clinical remission at Week 6 (maintenance phase, MP) was statistically superior, in the VDZ compared with the PBO arm. Here we report the results of predefined exploratory end-points for the MP: the effect of VDZ on time to disease worsening (TDW) and time to treatment failure (TTF).

Aims and Methods: Japanese pts with moderate-to-severe UC received 300mg VDZ or PBO at Weeks 0, 2 and 6 in the IP. Pts showing a clinical response to VDZ at Week 10 were then randomized 1:1 to receive VDZ (N = 41) or PBO (N = 42) in the MP, at Weeks 14, 22, 30, 38, 46 and 54. Disease worsening in the MP was defined as an increase of the partial Mayo score (range: 0-9 points) by ≥3 points compared with that of Week 10 for 2 successive visits, and a partial Mayo score of ≤5 points (or ≥6 points in 2 successive visits, in the case of >6 points at Week 10). Treatment failure was defined as any of the following: disease worsening, use of rescue medication, or study discontinuation due to drug-related adverse events.

Results: A Kaplan-Meier analysis of TDW showed that at Month 6, the proportion of pts without disease worsening was higher for the VDZ group (82.5%) compared with the PBO group (61.5%); this difference was sustained at Month 12 (89.6% vs 61.5%). The Kaplan-Meier analysis of TTD showed that at Month 6, the proportion of pts without treatment failure was 74.4%; this difference was maintained at Month 12 (74.4% vs 44.2%). Disease worsening in the VDZ group at Week 10 were then randomized 1:1 to receive VDZ (N = 73) or PBO (N = 71). The difference between the treatment groups for both TDW (p = 0.0446) and TTD (p = 0.0166).

Conclusion: VDZ showed statistically significant difference between treatment groups on TDW and TTD in Japanese pts with UC.

Introduction: Unlike anti-TNFs, ustekinumab (UST, an anti-IL-12/23 monoclonal antibody) appears minimally immunogenic, and therefore may not require combination with immunosuppressants (IS) AZA, 6-MP, or MTX to achieve maximum efficacy. As previously reported, UST is superior to PBO across a wide range of subgroups, including combo & mono therapy. In this post hoc

Abstract No: OP200

Disclosure: Nothing to disclose

The efficacy of UST in induction and maintenance was stratified according to IS use, then tested for potential correlation between the effect size of the response of UST and the use of IS (Chi-square, without correction for multiple comparison). For the safety population, we created odds ratios for all AEs and infections, for combo and mono groups. Safety data was corrected for follow-up and stratified by concomitant IS use.

**Results:** We compared the efficacy of UST and PBO at primary and major secondary endpoints for the induction and maintenance phase3 trials. During the induction trials (UNITI-1 & -2) we could not detect an association between concomitant IS use and efficacy at any endpoint (Data for approved -6mg/kg induction dose in Table 1), nor was there any consistently obvious benefit for combo over mono therapy during maintenance therapy (IM-UNITI, we failed to detect significant interactions between concomitant IS use and efficacy in either QSW or Q12W UST groups (Table1). Rates of total AEs were not obviously different between groups, though combo therapy tended to have lower rates than monotherapy, in terms of bleeding rates of infections, there were no trends when contrasting dose groups or IS use. PBO pts treated with concomitant IS had infection rates of 156, 182, and 114 per 100 pt-yrs (PBO, UST 90mg Q12W, and UST 30mg Q8W) vs. 167, 130, 173 per 100 pt-yrs (PBO, UST 90mg Q12W, and UST 90mg Q8W) without IS. Odds ratios did not appear different when contrasting mono and combo therapy, with 95% CI’s were broadly overlapping and crossing 1.0.

**Conclusion:** In our analysis, we were unable to detect a significant interaction between any dosage of UST and IS. Taken with previously presented data on serum [UST] being independent of IS use, and low overall immunogenicity; these data suggest that similar benefit is achieved when UST is administered as mono-therapy, or given as combination therapy with IS in patients with moderate to severe CD.

**Aims and Methods:**

Over 9 years to April 2017 analysis of LSL resected by EMR from a prospectively collected database at 8 Australian Tertiary Referral Centres was performed. LSL ≤ 25mm in the left colon and ≤ 20mm in the right colon were included. Multiple LSL in the same patient were excluded. Standard inject and resect EMR was performed. LSL resections were identified as piecemeal or en bloc (single snare resection) and their outcomes were compared. Scheduled surveillance colonoscopy was performed at desired intervals of 4-6 months and 18 months after EMR. Late recurrence described adenoma recurrence after a negative surveillance procedure.

**Results:** 587 LSL were included of which 267 (46.1%) were resected en bloc, with histologic clear margins in 80.4%. Larger and previously attempted LSL were more likely to be removed piecemeal (p=0.015 and p<0.001 respectively). Neither colonic location nor morphology predicted en bloc resection. En bloc resection took less time, median 10 versus 20 minutes, p<0.001. Muscularis propria injury was more common with en bloc resection (p=0.038). Other adverse events were not more common between the groups (table 1). LSL underwent first surveillance in rectum in 5 (2.6%) LSL which were resected en bloc and 23 (9.3%) resected piecemeal (p=0.004). 251 (63%) LSL underwent second surveillance at median 19.5 months (interquartile range 15.5–25). Recurrence was present in 1 (0.8%) EMR scar where the LSL was resected en bloc and 7 (2.7%) LSL which were resected piecemeal (p=0.066). In the piecemeal group 4/7 of these recurrences were after treatment of a previous recurrence. Need for surgery was infrequent in both groups during surveillance and was due to inability to resect recurrence in all cases.

Introduction: Cold snare polypectomy (CSP) for colorectal adenomas is used worldwide because of its excellent safety. However, the rate of R0 resection is not adequately high [1]. Few studies have reported on the efficacy of underwater endoscopic mucosal resection for colorectal adenomas [2]. We hypothesized that CSP for colorectal adenoma in underwater environment may combine high safety and high R0 resection rate; we named this procedure underwater CSP (UCSP). We prospectively analyzed the safety and efficacy of UCSP.

Aims and Methods: [Study 1] Between May 2017 and January 2018, 161 lesions from 53 patients were resected using UCSP. UCSP was carried out by two endoscopists who confirmed adenomas underwent follow-up colonoscopy 3 weeks after UCSP whether or not they achieved R0 resection. Any post-UCSP scars were biopsied to confirm the presence of residual adenomas.

[Study 2] We used propensity score-matching (PSM) analysis to compare the safety and efficacy of UCSP in the resection of 175 adenomas and to confirm the presence of residual adenomas in the 102 lesions resected using conventional CSP, between March 2015 and April 2017; the follow-up schedule for both groups was the same. The location, macroscopic type, and size of the lesions were used as covariates.

Results: [Study 1] The patients included 33 men and 20 women (mean age, 68.0 ± 8.1 years). The mean lesions in the colon, ascending colon, transverse colon, descending colon, sigmoidal colon, and rectum, was 15, 51, 53, 22, 35, and 15, respectively. The number of lesions with type Ip, Isp, Is, and H macroscopic appearance was 3, 49, 62, and 78, respectively. The mean lesion size was 4.5 ± 1.5 mm; median, 4mm. The en bloc resection and complete retrieval rates of specimens were 100% and 99.5%, respectively. In the final pathological diagnoses, 13, 157, 6, 8, 1, 1, and 4 lesions were non-tumor, low-grade tubular adenoma, low-grade tubulo-villous adenoma, high-grade tubular adenoma, high-grade tubulo-villous adenoma, intra-mucosal carcinoma, and SSA/P, respectively. The R0 resection rate of 177 tumorous lesions was 74.0% (131/177). No cases of perforation or delayed bleeding were found. Of the 177 scars post-CSP for adenomas, 175 (98.9%) were identified, and one residual scar was identified at UCSP site.

Conclusion: The R0 resection rate of UCSP was significantly higher than that of conventional CSP, with both procedures showing similar safety. Therefore, UCSP may be adequate therapy for small colorectal adenomas.

Introduction: Endoscopic full thickness resection (eFTR) of the colon using the full thickness resection device (FTRD) is a novel method for removing lesions involving, or tethered to, deeper layers of the colonic wall. The UK FTRD registry collects data from multiple centres performing this procedure. We describe the feasibility and early outcomes of this technique.

Aims and Methods: Registry data from April 2013 – January 2018 was analysed. Main outcome measures were technical success, procedural time, specimen size, R0 resection, endoscopic clearance, and adverse events. Reported technical difficulties were collated.

Results: 38 cases were performed across 8 centres (median 2 cases per centre, range 1-23). Mean patient age was 70 years (39-93). Indications for eFTR include non-lifting adenoma (18 cases), T1 tumour resection (10), submucosal tumour (7), and appendix base adenoma (3).

In 94.7% (37/38) of patients the lesion was reached with the FTRD. 1 caecal lesion could not be reached due to sigmoid diverticulitis. The procedure was technically successful in 91.9% of patients (34/37). Median procedure time was 41 minutes (11-86), median resection time 6 minutes (2-36), and median specimen size 22mm (10-30). R0 resection was achieved in 76.5% of patients (26/34). R0 resection was not achieved in 8 patients, of which 5 had no residual lesion on follow up, giving a total endoscopic clearance rate of 91.2% (31/34).

Technical difficulty occurred in 9 patients; due to snare failure and 3 due to lesion slippage on clip deployment. Of these 9 cases, 7 achieved R0 resection by using further snare.

Complications occurred in 2 patients; 1 acute appendicitis at day 6 after resection of appendix base adenoma, and 1 mild asymptomatic stricture at eFTR site at follow-up. There were no cases of bleeding, perforation, or fistula.

Conclusion: eFTR has a high success rate in treating lesions not previously amenable to endoscopic therapy. Whilst technical difficulties may arise, complication rates are low and outcomes acceptable, making eFTR a viable alternative to surgery.

Introduction: Among early colorectal carcinomas, lesions with little possibility of lymph node metastasis are usually treated endoscopically [1]. However, to the best of our knowledge, no report has described the problem with endoscopic treatment for early carcinomas arising in sessile serrated adenoma/polyp (SSA/Ps). Although invasive carcinomas with SSA/Ps (CA-SSA/Ps) are rare, these tumours are critical because SSA/Ps may grow into subsequent SSA/Ps with high-grade dysplasia or those with submucosal carcinoma more rapidly [2]. Furthermore, mucinous histology has also been found in CA-SSA/Ps [3, 4].

Aims and Methods: The aim of this study was to elucidate the clinicopathological features of CA-SSA/Ps and to investigate the possibility of endoscopic resection for these lesions. We reviewed all lesions pathologically diagnosed as T1 colorectal carcinomas that were endoscopically or surgically resected at Juntendo University Hospital and our affiliated hospitals between 2006 and 2017. We identified 45 CA-SSA/P lesions (from 45 patients) that were endoscopically (n = 18) or surgically resected (n = 27). For comparison, we randomly selected 200 invasive carcinomas with adenomas (CA-ADs) that were endoscopically (n = 87) or surgically resected (n = 113) from 200 patients.

Results: The clinicopathological characteristics of the studied lesions are summarized in Table 1. The patients with CA-SSA/P were older than those with CA-ADs (median age, 74 years vs. 57 years). Although the R0 resection rate of UCSP was significantly higher than that of CSP (75.5% vs. 32.4%; p < 0.001), the rate of pathological residual adenomas 3 weeks after resection was 0.98% in both groups (1/102).

In 97.4% (37/38) of patients the lesion was reached with the FTRD. 1 caecal lesion exhibited a higher potential for lymphatic invasion and lymph node metastasis. Therefore, the risk of lymph node metastasis should be considered when perform-

OP206 ENDOSCOPIC RESECTIONS IN INFLAMMATORY BOWEL DISEASE

1, A. Alkandari1, M. Bhandari1, A. Przybysz2, M. Bugajski2, K. Kandiah3, S. Subramaniam1, R. Maselli4, P. Galtieri4, M. Spychalski5, S. Lof8, F. Giovinazzo8, J. van Dam9, T. Kent2, O.R.C. Busch10, B. Groot Koerkamp11, M. Abu Hilal11, C. Bassi12, J. Tseng7, M.G.H. Besselink13

Aims and Methods: The aim of this study was to assess the need for surgery in the management of neoplasia in colitis. This is a multicentre cohort study of all neoplasia endoscopically resected in patients with colitis from 5 tertiary European centres between 2008-2017. The following endoscopic resection techniques were used: endoscopic mucosal resection (EMR) and hybrid endoscopic submucosal dissection (ESD).

Results: 101 neoplasia were resected in 85 patients at 5 European centres. Mean age 61 years (range 28-82). Mean size of lesions 34 mm (range 8-120mm). 40% of the lesions were treated by hybrid ESD. There was no difference in lesion location between EMR and hybrid ESD. Lesions >20mm in size were removed more by hybrid ESD than EMR. More of the lesions removed by hybrid ESD (26) had fibrosis compared to EMR (15). 7 complications occurred in the cohort; 3 cases of bleeding and 4 perforations. Bleeding was controlled endoscopically, 3 perforations were managed endoscopically and 1 required surgery. 7/86 (8.1%) lesions with follow up data had recurrence.

Multi-variate regression analysis concluded;
- EMR leads to higher recurrence rates, irrespective of size, location and fibrosis (p-value of 0.048)
- Hybrid ESD leads to higher complication rates in the colon compared to the rectum (p-value of 0.045)
- Hybrid ESD shows a trend towards better en-bloc resection (p-value 0.063)
- 5 lesions underwent surgery; 3 due to cancer; 1 due to perforation; 1 due to failure of endoscopic resection. Histology: 88 adenomas (low-grade dysplasia), 6 adenomas (high-grade dysplasia), 3 cancers and 4 sessile serrated polyps.

Conclusion: This is the largest reported cohort of endoscopic resections of neoplasia in colitis. We demonstrate that both hybrid ESD and EMR are feasible in colitis with only 5% of patients requiring surgery. Fibrosis is very common in colitis. Recurrence is higher with EMR and complications higher with hybrid ESD. Our data shows that lesions with fibrosis are best treated by hybrid ESD, and those without fibrosis and <20mm in size can be managed by EMR.

Thorough analysis of human and mouse pancreatic tissues showed that GKN1 expression is absent in healthy pancreatic cells and on malignant tumors. Furthermore, GKN1 expression is restricted to low-grade premalignant lesions, it is abundant in the cytoplasm of dysplastic epithelium. Proteomic analysis in KC mice confirmed the secretion of GKNs into pancreatic juice but not in the serum. Analysis of pancreatic tissue from GKN1−/− KC mice, at 3 months, showed faster development of PanIN with accelerated tumor development. Investigating the cellular and molecular mechanisms focused on tissue remodeling (epithelial mesenchymal transition, tight junctions), apoptosis, senescence and inflammatory environment. GKN1−/− mice injected with Pan02 cells developed significantly smaller subcutaneous tumors, possibly due to increased CD8+/CD4+ T cells ratio within tumors.

Conclusion: Collectively, our data establishes a role for Gastrokine 1 in PanIN and PDAC development. The accelerated PanIN development in the absence of GKN1 in vivo suggest that gaskrokines expression can delay PanIN formation and molecular tumor markers focused on tissue remodeling (epithelial mesenchymal transition, tight junctions), apoptosis, senescence and inflammatory environment during carcinogenesis could make them potential early biomarker(s) to detect PDAC.

Conclusion: lung endothelium and not of the liver endothelium. Comparative secretomic the selective promotion of lung endothelial growth by cancer cell subgroups. In human PCa patients and from the genetically engineered KPC ( introduction: Pancreatic cancer is characterised by an unparalleled degree of neural invasion (NI). NI is associated with reduced overall survival, increased local recurrence rate, and with neuropathic pain. One of the major mechanisms leading to NI is the specific affinity of tumor cells to neurons. This affinity can be mimicked by means of 3-dimensional migration assays that include neurons and cancer cells.

Aims and Methods: The aim of the study was to identify genetic alterations that specifically promotes neural invasion in pancreatic cancer by means of in vivo piggyback-transposon mutation. A set of genetically pre-characterized mouse pancreatic cancer cell lines, which were generated by means of piggyback-transposon mediated mutagenesis, was used in three-dimensional migration assays with neurons. The cell lines with the highest affinity to neurons were analyzed for the sites of transposon integration in a pre-existing sequencing data base. The identified loci were functionally analyzed in the cells by means of Cre/ Cso9 gene editing.

Results: In the genetically pre-characterized group of 22 mouse pancreatic cancer cell lines, 3 cell lines were identified to exhibit a high neuroaffinity. In the analysis of the transposon insertion sites, we found a specific pleckstrin domain in the gene. In accordance, Crisp/Cas9-mediated gene editing resulted in increased migration of pancreatic cancer cell to Neurons.

Conclusion: The in vivo mutation screen allows identification of neural invasion-promoting genetic alterations in pancreatic cancer. These results suggest that galactoaminyltransferases may promote neural invasion in pancreatic cancer.

Introduction: Barrett’s oesophagus (BE) is an intestinal metaplasia characterized by crypt-structured columnar epithelium with distal gastrointestinal (GI)-tract characteristics. This hemochronic transformation predisposes to adenocarcinoma of the esophagus. HOX genes are known mediators of hemochronic transformations. Certain HOX genes of anterior to posterior progression in organogenesis and tissue homeostasis. The 3 to 5’ sequence of HOX genes corresponds to the sequence in which they act along the anterior toward posterior axes of the body. This property termed collinearity and links clustering of HOX genes with anterior to posterior progression in organogenesis and tissue homeostasis. Recent evidence from human and mouse studies has shown BE might originate from the glands at the gastro-oesophageal junction (see refs). It can be shown that these glands contain elements associated with positional misspecifica-

Introduction: Pancreatic cancer (PCa) has the worst prognosis among all gastro-intestinal cancers. Recent studies identified a remarkably better prognosis of PCa patients with isolated pulmonary metastasis. The reason behind this peculiarly better prognosis of this interesting patient subgroup is yet unknown.

Aims and Methods: In the present study, we hypothesized that some subtypes of PCa might preferentially foster the growth of endothelial cells in the lung, and lead to the growth of lung and thereby lead to isolated pulmonary metastases. For this purpose, we made use of endothelial cells specifically isolated from the human lung and liver, and treated these with several types of human pancreatic cancer cell lines. The proliferation and the tube formation rate by each PCa cell line was shown in cancer cells within lung metastases and relatively higher levels of Angpt2. In vitro, certain types of PCa cell lines preferentially induced the growth of lung endothelium and not of the liver endothelium. Comparative screctomic analysis of lung and liver endothelium growth-promoting molecules showed selectively increased secretion of plasminogen and transferrin from cancer cells that specifically promote lung endothelial growth.

Conclusion: Occurrence of isolated pulmonary metastasis in PCa may be due to the selective promotion of lung endothelial growth by cancer cell subgroups. In this pulmonary pro-angiogenic capacity of PCa cells, plasminogen and transferrin may be among the key mediators.

Disclosure: Nothing to disclose.

Disclosure: may be among the key mediators.
Conclusion: HOXA13 expression is epithelial and is not upregulated in squamous epithelium in vitro and in vivo. The HOXA13 promoter is regulated bipartially by the Wellman and the non-Wnt mediated pathway. These findings point to a novel role of Notch signaling in NFkB dependent stem cell expansion during esophageal carcinogenesis and introduce Notch activation as a novel biomarker for BE to EAC progression.

Introduction: Barrett’s esophagus (BE) is a premalignant, inflammation-dependent condition of the esophagus and a known precursor of esophageal adenocarcinoma (EAC). The incidence of EAC has increased at a rate of 4 to 10% annually in parts of the Western World. Though endoscopic surveillance is utilized to detect and treat dysplasia and early malignancy, it may not detect early cancers in nearly half of patients. Furthermore, endoscopic therapy shows decreased ability in only up to 75% of cases and treatment specific risks have to be factored in. Novel biomarkers would ideally help in identifying patients with BE at increased risk of disease progression, prompting extended surveillance programs. A number of predictive markers have been reported in the literature including DNA content abnormalities. Genomic instability is a known driver for carcinogenesis and can occur with impaired telomere function. However, the functional role of short telomeres has not been evaluated during esophageal carcinogenesis.

Aims and Methods: Here we utilize the L2-IL-1β1/2 transgenic mouse model of BE that recapitulates the human histopathologic progression to EAC while inducing chronic inflammation in the esophagus. To study the role of telomere dysfunction and shortening of telomeres we crossed a telomerase k.o. mouse model (mTerc-/-) into our IL-1β1/2 model and analyzed progression to dysplasia as well as its implication for cellular differentiation in different backcrossed IL-1β1/2 generations. Telomere length was measured quantitatively with in situ Hybridization (FISH) on a per cell basis. Results were compared to a human cohort of which full-length resected surgical esophagi were histopathologically scored and epithelial telomere length was measured at different stages of disease for each individual (27 samples of 9 individuals).

Results: In the mouse model, significant dysfunction of telomeres was observed in the second generation (H1-mTerc-/- G2). Therefore, we compared IL-1β1/2 mTerc-/- G2 mice (n=16) with IL-1β1/2 mice (n=16). IL-1β1/2 mTerc-/- G2 mice exhibited significantly shorter telomeres (p=0.02) and a significantly higher grade of dysplasia (p=0.02) than their age-matched IL-1β1/2 counterparts. These length assessment of human biopsies of EAC precursor lesions confirmed prior findings that BE- and LGD- epithelial cells possess significantly shorter telomeres than epithelial control cells of the gastric cardia with reduced ratios in BE and LGD. Furthermore, telomeres (p<0.01) and LGD-Cardia (p<0.01) samples, suggesting a progressive shortening with accelerated malignant transformation. Importantly, discrimination of epithelial cells into columnar cells and goblet cells displayed significantly shorter telomeres in columnar lined cells than in goblet cells of human BE tissue (p<0.01) and LGD tissue (p=0.01).

Conclusion: Shortening of telomeres accelerated dysplasia in our mouse model of BE. This proves for the first time the functional importance of dysfunctional telomeres as a potential driver in early stages of esophageal carcinogenesis. In addition epithelial telomere shortness was correlated with disease progression and cellular de-differentiation in murine and human EAC precursor lesions. Thus telomere length qualifies as a potential biomarker in EAC precursor lesions and should therefore be further tested in large human cohorts to prove its validity. Remarkably the result that goblet cells possess longer telomeres than columnar cells within the same histologically defined samples complements earlier findings that higher goblet-to-columnar-cell ratios are more likely to be found in stages of metaplasia than dysplasia.

References
to differentiating patients with a normal oesophagus from those with DBE and OAC. We demonstrate that raised MCM5 expression in exfoliated cells of patients in the NDBE group demonstrated very high expression compared to the DBE/OAC group, although 2 patients in the NDBE group showed a trend towards higher mean MCM5 expression in patients with DBE/OAC (2.72 pg/ml IQR 5.4–9.9) of 628 patients included (69% male, median age 60 years, 76% length of BE ≥ 3 cm); 48 developed HGD or EAC. If a patient would have only 2 FU moments, 1 with normal (0) expression of the biomarker, 1 with aberrant (1), the hazard ratio (HR) of neoplastic progression was 1.2 for LGD (p = 0.06). There was no significant difference between patients with a macroscopically normal oesophagus (NE), non-dysplastic Barrett’s oesophagus (NDBE), dysplastic Barrett’s oesophagus (DBE) and OAC.

**Aims and Methods:** Patients were recruited from a UK referral centre between Aug 2017 and Apr 2018. All patients with NDBE, DBE or OAC had endoscopic and histological confirmation of the diagnosis. High-grade dysplasia was considered DBE. Patients previously treated with radiofrequency ablation, chemotherapy or chemo-radiotherapy, with systemic inflammatory disease, BE low-grade dysplasia, BE high-grade dysplasia or other malignancy were excluded. The oesophagus was carefully intubated to stratify symptomatic patients presenting to clinicians. We assess whether MCM5 expression, quantified using a proprietary assay, can be used to discriminate between patients undergoing endoscopy with a macroscopically normal oesophagus (NE), non-dysplastic Barrett’s oesophagus (NDBE), dysplastic Barrett’s oesophagus (DBE) and OAC.

**Results:** 61 patients were recruited (15 NE, 14 NDBE, 18 HGD and 14 OAC). We demonstrate a stepwise increase in MCM5 expression for patients with acid reflux, NDBE, DBE and BE associated OAC. The median expression for each group was 47 pg/ml (IQR 32.8 [26.92–59.77]) for NE, 116 pg/ml (IQR 411.3 [17.23–428.54]) for NDBE, 229 pg/ml (IQR 1070.4 [29.59–1099.96]) for DBE and 279 pg/ml (IQR 1462.7 [10.09–1500]) for OAC. There was a significant difference in MCM5 expression between patients with a macroscopically normal oesophagus and those with DBE or adenocarcinoma (p < 0.001). We also observed a trend towards higher mean MCM5 expression in patients with NDBE compared to those with a normal oesophagus (p = 0.06). There was no significant difference between patients with NDBE and DBE/OAC, although 2 patients in the NDBE group demonstrated very high expression compared to the rest of the group.

**Conclusion:** We demonstrate that raised MCM5 expression in exfoliated cells obtained from aspirating gastric fluid at upper endoscopy is a feasible approach to differentiating patients with a normal oesophagus from those with DBE and OAC. Further work should focus on appropriately powered multi-centre trials to assess for significant differences in MCM5 expression in patients with AR (NE), NDBE, DBE and BE associated OAC.

**Disclosure:** Materials and assays were performed by Arquer.
A new class of acid-suppressing agents, and takes only 3 hours to inhibit gastric acid secretion. Therefore, VPZ should be first administered shortly after ESD for pre-ESD bleeding.

Results:

Conclusion: Vonoprazan should be first administered shortly after ESD for preventing post-ESD bleeding.

administration of anticoagulants after April 2013. The clinical outcomes of ESD were retrospectively compared between the non-continuous and continuous groups.

Results: The study population included 60 men and 16 women (median age, 77.5 years). Varifarin was taken by all 49 patients in the non-continuous group and 16 patients in the continuous group. The remaining 11 patients received DOACs (dabigatran, n = 3; apixaban, n = 4; and rivaroxaban, n = 4). The clinical characteristics (including age, gender, tumor location, macroscopic appearance, tumor size, presence of ulcer scar and tumor depth) did not differ between the two groups to a statistically significant extent. En-bloc resection was achieved in all patients with a complete resection rate of 96% in the non-continuous group (47 of 49 patients) and 100% in the continuous group (27 of 27 patients). The median procedure time was 78 minutes in the non-continuous group and 70 minutes in the continuous group (p = 0.09). Postoperative bleeding occurred in 4 patients in the non-continuous group (8.2%) and 2 patients in the continuous group (7.4%); the difference was not statistically significant (p = 1.00). None of the patients developed perforation during the study period. One patient in the non-continuous group suffered from cerebrovascular disease.

Conclusion: The continuous administration of anticoagulants did not significantly increase the incidence of adverse events in our cases. Considering the risk of cerebrovascular disease, the continuous administration of anticoagulants might be feasible and safe in gastric ESD.

Disclosure: Nothing to disclose.

OP223. EFFICACY OF ORAL MIXTURE OF HYDROCORTISONE SODIUM SUCCINATE AND ALUMINUM PHOSPHATE GEL FOR THE PREVENTION OF STRICTION AFTER ≥2/3 CIRCUMFERENTIAL ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR ESOPHAGEAL CANCER

Y. Huang, X. Yan, D. Nie
Peking University Third hospital, Beijing, China

Contact E-Mail Address: 13911765322@163.com

Introduction: ESD has been performed on many patients with early esophageal cancer. However, postoperative stricture after ≥2/3 circumferential ESD is the most important issues for quality of life in patients which is drastically decreased and repeat, periodic endoscopic balloon dilation (ESD) is usually required. We explored an innovative strategy of oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel for prevention of the stricture and evaluate the efficacy of this mixture in single center of Beijing, China.

Aims and Methods: 27 patients who underwent more than 2/3-circular ESD between September 2014 and December 2017 were enrolled. They were randomized into control and study groups. 13 patients received endoscopic intraluminal steroid injection accompanied with systemic steroid treatment (IT + ST, group control); 14 patients received oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel (IT + ST group. Start with 0.5g oral mixture hydrocortisone sodium succinate and aluminum phosphate gel 20g qid, qid 2 weeks and continued with a gradually tapering dose of OHA on the second day post-ESD. ESD was performed when patients experienced persistent dysphagia. If the patient had no complaint of dysphagia, esophageal gastroduodenoscopy (EGDY) was performed 8 weeks after ESD to evaluate any possible stricture. The primary end point in this study was the stricture rate after ESD. The secondary end point was the number of EBD sessions required to resolve the stricture. A stricture was defined as a difficulty in swallowing solids or an inability to pass an EGD (9.2mm diameter endoscope).

Results: No significant differences were seen among the 2 groups in terms of demographic parameters including age, sex, tumor location, resection size. The stricture rates of IT + ST, OHA group after ESD were 53.8% (7 of 13 patients), 71.4% (1 of 14 patients), respectively (95% confidence interval, p = 0.013). OHA group needed less EBD sessions than IT + ST group (median 0, interquartile range 0 to 0 vs. median 1, interquartile range 0 to 5, p = 0.019).

Conclusion: Oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel showed promising results for the prevention of stricture after ESD for early esophageal cancer.

Disclosure: Nothing to disclose.

OP224. A RANDOMIZED CONTROLLED ANIMAL STUDY TO EVALUATE THE TECHNICAL FEASIBILITY OF CHEMICALLY INHIBITED SUBMUCOSAL DISSECTION TECHNIQUE WITH THE CONTINUOUS APPLICATION OF MESNA

A. Koizumi
Jikei University School of Medicine, Endoscopy, Tokyo, Japan

Contact E-Mail Address: akio_a60@hotmail.co.jp

Introduction: Mesna is a mucolytic agent, which chemically dissolves disulfide ESD procedure to create a submucosal fluid bleb, which dramatically reduces the need for electrosurgical dissection. However, the chemical effect of mesna is inactivated within a short period of time and the substance with a low osmotic pressure quickly dissipates into surrounding tissues. A novel infusion pump system was recently developed to enable mesna to be continuously applied onto tissues while dissection the submucosal tissue plane.

Aims and Methods: To explore the procedural feasibility of ESD with the chemical blunt dissection technique (COLD ESD) using the newly developed mesna infusion pump system (CADISS Remote System, Auxin surgery) in vivo porcine models evaluating the effect of mesna as a chemical tissue dissector comparing with saline. In this study, 5 porcine models were used under general anesthesia. We created 2 tentacles sized about 20mm in the body and the antrum of the stomach respectively. A total of 4 lesions were created for each pig. Then, each lesion was randomly assigned into the mesna group or the saline group as a control. After the circumscription around the lesion was made, mesna or saline was injected into the submucosal layer underneath the isolated lesion with the CADISS Remote System. The information of the injectate used was blinded to the operator. First, the blunt cleavage of the submucosa was attempted while continuously applying one of the injectates using a Hook Knife J (Olympus medical systems), connected to the pump. However, the use of electrosurgical dissection was allowed when the operator felt excessive tissue resistance ad lib. We counted the number of electrosurgical incisions used with the VIO Doku software in real-time (ERBE). All endoscopic procedures were performed by experienced endoscopists. The levels of procedural difficulty were evaluated with a 5-point analogue scale. The burned area ratio (burned area/specimen area) of the excised specimen was evaluated with a picture of the specimen using Image J software (NIH).

Results: En bloc resection rate was 100% in both groups. The total procedure time (mesna group 18.1 ± 7.9 min vs. saline group 20.9 ± 12.5 min, p = 0.54), the submucosal dissection time (mesna group 11.1 ± 8.0 vs saline group 12.5 ± 9.4

Introduction: Laparoscopic pancreatoduodenectomy (LPD) is gaining popularity because of potential advantages including less operative blood loss, less delayed gastric emptying, and shorter hospital stay but concerns exist regarding increased pancreatic fistula rates and, in low-volume centers, increased postoperative mortality. Multicenter randomized trials investigating this subject are lacking. In the Netherlands, LPD was introduced according to the IDEAL framework for surgical innovation including a training program (LAELAPS-2) with a 3.5% 90-day mortality. Multicenter randomized trials investigating this subject are lacking. In the Netherlands, LPD was introduced according to the IDEAL framework for surgical innovation including a training program (LAELAPS-2) with a 3.5% 90-day mortality. Multicenter randomized trials investigating this subject are lacking. In the Netherlands, LPD was introduced according to the IDEAL framework for surgical innovation including a training program (LAELAPS-2) with a 3.5% 90-day mortality. Multicenter randomized trials investigating this subject are lacking. In the Netherlands, LPD was introduced according to the IDEAL framework for surgical innovation including a training program (LAELAPS-2) with a 3.5% 90-day mortality. According to the IDEAL framework, we hereafter initiated an RCT to assess whether LPD could reduce time to functional recovery.

Aims and Methods: A multicenter randomized controlled, patient-blinded, trial comparing LPD with OPD was performed in 4 centers that each perform ≥20 pancreatoduodenectomies annually (median 37 (range 23-77)), completed the LPD training program, and had performed at least 20 LPDs during the 18 months prior to the start of the trial (range 23-34). Adult patients with an indication for pancreatectomy because of a neoplasm without signs of vascular involvement were included. Primary outcome was time (days) to functional recovery.

Results: The data safety monitoring board (DSMB) recommended early termination were included. Primary outcome was time (days) to functional recovery. The results of this study indicated that the continuous topical application of mesna would minimize the thermal damage on the tissues, which may provide optimal tissue sampling for accurate histological evaluation of specimens and reduce bystander tissue burns associated with electrosurgical incisions.

Disclosure: Nothing to disclose.
**OP227** WIRE-GUIDED BILIARY CANNULATION IN ENDOSCOPIC RETROGRADE CHolangiopancreatography (ERCP): A PROSPECTIVE RANDOMIZED COMPARISON BETWEEN MICRO AND CONVENTIONAL GUIDEWIRE

A. Mori, S. Ito, S. Hayashi, T. Shibuya, H. Hachiya, T. Yumura, N. Ohashi Ichinomiya Nishi Hospital Dept. of Gastroenterology, Ichinomiya, Japan

Contact E-Mail Address: a-mori@anzu.or.jp

**Introduction:** Wire-guided biliary cannulation is reported to be an appropriate first attempt treatment technique, since it is associated with a high success rate and low risk of post-ERCP pancreatitis (PEP). However, the conventional guidewire (CGW) (0.025 inch) is sometimes too rigid to pass through the long curved narrow segment, resulting in increased biliary cannulation time and even an unsuccessful biliary cannulation. At UEWG 2017, we reported that a micro guidewire (GTW; GT wire; 0.016 inch, 300 cm, TERUMO, Japan) designed for selective angiography was helpful in such cases. Rapid biliary cannulation is desirable because a prolonged procedure may induce PEP. The use of GTW-assisted cannulation as the first-time cannulation technique for ERCP could reduce biliary cannulation time.

**Aims and Methods:** We aimed to evaluate whether biliary cannulation was achieved in lesser time using GTW than when using CGW in ERCP. In total, 118 consecutive ERCP-naive patients were randomly assigned to undergo biliary cannulation with GTW (GTW group) or CGW (CGW group). We measured the cannulation time (from the time the cannula advanced out of the endoscope channel to the time successful deep cannulation was confirmed) and the serum amylase level on the following day. The endoscopist performed ERCP with the designated guidewire for less than 10 min and was permitted to switch to the other guidewire to achieve cannulation after 10 min from initiation of the procedure. The secondary outcome was the overall success rate of biliary cannulation as well as the incidence of PEP and asymptomatic hyperamylasemia in both groups. Additionally, among patients in whom biliary cannulation was successful, we compared the frequency of switching to the other guidewire and the biliary cannulation success rate between both groups.

**Results:** The biliary cannulation success rate within the first 10 min was significantly higher in the GTW group than in the CGW group (39/59 patients, 66% and 29/59 patients, 49%, respectively; p = 0.047 by Fisher’s exact test). The overall biliary cannulation success rate (57/59 patients, 97% and 57/59 patients, 97%) and incidence of PEP (1/59 patients, 1.7% and 1/59 patients, 1.7%) was equal in both groups. The overall asymptomatic hyperamylasemia was 13.6% (8/59 patients) in the GTW group and 15.3% (9/59 patients) in the CGW group. Among the 114 patients in whom biliary cannulation was successfully achieved, 32% (18/57 patients) in the CGW group were switched to GTW. No patients in the GTW group were switched to CGW after 10 min from initiation of the procedure. The biliary cannulation success rate in the GTW group was significantly higher than that in the CGW group (p = 0.036, by the Kaplan-Meier method and log rank test).

**Conclusion:** The use of GTW-assisted cannulation as the first-time cannulation technique for ERCP significantly improved the biliary cannulation success rate and reduced biliary cannulation time.

**Introduction:** Colon polyp detection and optical biopsy are key performance indicators in colonoscopy. Artificial Intelligence (AI) has the potential to greatly improve both. However, practical real-time applications with standard scopes are lacking.

**Aims and Methods:** We have published on real-time optical biopsy of diminutive colon polyps using AI, surpassing the 90% negative predictive value (NPV) for adenomas, as per PIVI guidelines. We sought to use latest AI techniques to further improve our optical biopsy performance. In relation to polyp detection, most AI detection tools are trained using still images or videos with obvious polyps. In contrast, we planned our tool around difficult sequences from clinical screening videos that start when the polyp first becomes visible. Finally, an AI model capable of detecting NBI light was the cornerstone that allowed us to propose a “full clinical workflow” for colon polyp detection immediately followed by optical biopsy. Our workflow was optimized to allow for real-time clinical use, a first in this field.

The workflow captures the video feed from a tower and consists of 3 distinct AI models: a NBI light detector, a polyp detector, and an optical biopsy. The NBI light detector runs continuously and triggers either the detection mode (white light) or the optical biopsy mode (NBI). This allows a seamless interface without the need for a switching signal from either the tower or operator.

**Results:** The NBI light model was tested on 21,804 unseen frames and achieved a near-perfect accuracy of 99.94%.

The polyp detection model was tested on the polyp approach sequence part of 30 previously unseen colonoscopy videos (>20min each). The model detected polyps with a sensitivity of 79.6% while triggering on 13.7% of frames without polyps. Notably, polyps are detected, on average, 403 milliseconds after their first appearance.

The optical biopsy was tested on videos of 125 previously unseen polyps and achieved a sensitivity of 95.95%, specificity of 91.66%, and NPV of 93.6%. Even if the model can abstain when unsure, it committed to a prediction for 97.6% of polyps, an absolute increase of 12.8% over our previous work.

Finally, results are displayed in real-time and the user interface is updated 30 times per second.

**Conclusion:** We propose the first real-time AI full colonoscopy workflow for automatic detection followed by optical biopsy of colorectal polyps. It consists of three separate AI models allowing for real-time detection of colon polyps, automatic recognition of the switch from white light to NBI, followed by immediate optical biopsy of detected polyps. Detection shows very promising results, especially on difficult approach sequences, and our AI optical biopsy has been even further improved. A clinical trial is planned for the near future.

Introduction: Implementation of the optical diagnosis of diminutive polyps increases the efficacy and reduces the economic burden of a colorectal cancer (CRC) screening program. To adopt such strategy in clinical practice, the ASGE PIVI thresholds should be met: >90% negative predictive value (NPV) for diagnosis of adenomatous histology and >90% agreement between optical diagnosis and histological diagnosis in determining the post-polypectomy surveillance intervals. We evaluated these performance parameters in the Dutch CRC screening program.

Aims and Methods: We measured the agreement between optical diagnosis and histological diagnosis in determining the post-polypectomy surveillance intervals. We evaluated the diagnostic performance of optical diagnosis compared with histological diagnosis in 2390 index colonoscopy procedures in 2015/2016. Agreement on surveillance intervals was calculated using kappa statistics. Diagnostic performance of optical diagnosis and histological diagnosis was compared using the McNemar test and the Methodological Index for Research Quality (MIRQ) tool was used to rate studies.

Results: Overall agreement on surveillance intervals was 0.666 (95% CI 0.634-0.698). Baseline characteristics of patients included in this study were: median age: 65 years (50-75), 54% male, 33% patients had a personal history of colorectal cancer, 5% smokers, and 42% were on aspirin therapy. The diagnostic performance of optical diagnosis compared with histological diagnosis is shown in Table 1.

Conclusion: The optical diagnosis of diminutive polyps is feasible in routine clinical practice. However, the diagnostic performance and decision-making algorithm on surveillance intervals need improvement. Further studies are indicated to improve the diagnostic performance and to optimize the efficacy of our nationwide CRC screening program.

2Leeds Teaching Hospitals NHS Trust, Gastroenterology, Leeds, United Kingdom

Contact E-Mail Address: richard.lord2@nhs.net

Introduction: Patients with ulcerative colitis (UC) and Crohn’s colitis are known to have an increased risk of colorectal cancer compared with that of the background population. The recent National Institute for Health and Care Excellence (NICE) guidelines for colorectal cancer screening in patients with inflammatory bowel disease (IBD) recommend colonoscopic surveillance of patients with IBD, based on its definition of high-risk groups, without defining specific colorectal cancer surveillance intervals or strategies. We present the interim analysis of a randomized clinical trial investigating the efficacy of different methods of surveillance in patients with IBD.

Aims and Methods: A parallel group randomized controlled trial (ClinicalTrials.gov id: NCT03250708) in which patients undergoing surveillance for IBD colitis were randomized to receive: 0.2% IC using a spray catheter or HDCE using 0.3% IC via a foot pump. HDCE was performed using the Olympus CF-HQ290i and processors (Elite CV 290). A total of 221 patients were randomized to 0.2% IC and 0.3% IC arms in the study.

Results: There were 75 patients in each arm (total n = 150). Baseline characteristics were similar between the two arms except for sex distribution which was significantly different: 58% male in the 0.2% IC arm and 42% male in the 0.3% IC arm (p = 0.012). Dysplasia was reported in 5 (3.3%) cases in the 0.2% IC arm and 2 (1.3%) in the 0.3% IC arm (p = 0.083). Dysplasia on random biopsies, only, was found in 3 (2%) of the cohort. Histopathologists confirmed presence of dysplasia. Time of withdrawal and ampoules of IC were also recorded.

Conclusion: There is no significant difference in dysplasia detection between 0.2% and 0.3% IC, which suggests that a reduction in cost of surveillance is possible. A definitive trial is needed to confirm these preliminary results.

Introduction: Adenoma recurrence after wide field endoscopic mucosal resection (EMR) of laterally spreading colorectal lesions ≥ 20mm (LSLs) is a major limitation. Data on the optimal methods and outcomes of endoscopic treatment of recurrence (ETOR) is absent and no evidence based standard exists. We examined the techniques and success of ETOR over time in a large prospective cohort.

Aims and Methods: Over 100 months to January 2017 data on all recurrences after consecutive EMR procedures for LSLs at the lead centre of the Australian Colonic Endoscopic Resection Study (ACE) were recorded. Recurrence at the EMR site was deemed a 1st recurrence. Further hand-drawn high definition endoscopic imaging as previously described. ETOR comprised coagulation snare resection 2 recurrence (ERBE Effect 2, 30W), cold avulsion forceps with adjuvant snare tip soft coagulation [CAST] (ERBE Effect 4, 80W) or a combination of the two. The primary outcome were complete adenoma clearance using ETOR at first surveillance (desired interval 4-6 months) and absence of recurrence at subsequent surveillance procedures.

Results: 1558 patients with 1558 LSLs were included. 150 LSLs (9.6%) had recurrence at first surveillance colonoscopy. The mean age of patients with recurrence was 68 years and 55% were male. Recurrent LSLs were median 50mm in size (IQR 35-60mm) and located distal to the hepatic flexure in 52.7%. They were commonly Paris 0-IIa+Is morphology (46.7%) and displayed tubulovillous architecture (75.3%), with high grade dysplasia in 23.4%. 3 (2.7%) were resected en-bloc. Recurrence at the EMR scar was ≤ 2mm in size (64%), uni-focal (75%) and within the scar (55%) or at the edge (45%). The commonest modality used to resect recurrence was hot snare with adjuvant snare tip soft coagulation (CAST) used in 30% and was also used in combination with hot snare (9%). CAST was more commonly used in the second temporal half (62.5%) than the first half (10.6%, p < 0.001) of the cohort. Prior injection was performed in a minority (16%). In 124 cases (86.7%) cases where tissue was retrieved, there was histologic confirmation of recurrence. ETOR achieved complete clearance of recurrent adenoma in 94.7% of cases at first surveillance colonoscopy with 5 (5.3%) referred for surgery primarily due to an

[Table 1: Features of LSLs that demonstrated recurrence at first surveillance
colonoscopy and their outcomes, FU – follow up, SC1 – first surveillance]
Conclusion: Adenoma recurrence after EMR of LSLs is commonly diminutive
and can be effectively treated using simple endoscopic techniques with rates of
long-term remission approaching 90%. Based on this data, more technically
complex, morbid and resource intensive endoscopic or surgical techniques are
unnecessary to resect LSL recurrence after EMR.

[Intraprocedural bleeding during ESD]
Both groups were well matched in terms of baseline characteristics (mean lesion
size 33.7mm in the PurastatÕ group and 36.6mm in the control group, age 68.6 vs
71.5 years, adenocarcinoma and high-grade dysplasia 60.9% vs 53.3%). There
were 221 bleeds requiring haemostasis in the PurastatÕ group compared to 262 in
the control group with no significant difference in the mean number of bleeds per
patient. There was a significant reduction in the proportion of bleeds treated with
heat therapy in the patients receiving PurastatÕ compared to controls (110/221 or
49.8% vs 261/262 or 99.6%, p 5 0.001). PurastatÕ was used in 54.8% of bleeds in
the interventional group and haemostasis was achieved with this device as a
single agent in 91.7% (111/121) of cases when used.
All bleeds were managed endoscopically with no blood transfusion or hospital
admission for management required. There were no complications related to the
application of PurastatÕ in this study and it did not interfere with subsequent use
of diathermy for haemostasis if required.
Conclusion: This is the first randomised controlled trial of this haemostatic device
and our results show that PurastatÕ successfully reduced the use of intraprocedural heat therapy for haemostasis in ESD by almost 50%. The device was easy
to use and did not prolong the time taken for haemostasis or the total procedure
time. This study supports its use as a safe and effective haemostat for bleeding
during endoscopic resection.

Introduction: Endoscopic submucosal dissection (ESD) is associated with intraprocedural bleeding which is usually treated with heat applied to the visible
bleeding vessel. Prolonged and repeated applications of heat can increase the
risk of perforation. PurastatÕ is a transparent gel with a novel extracellular
scaffold matrix which forms a mechanical barrier over the bleeding point. It
may be an alternative non diathermic option for intraprocedural bleeding.
Aims and Methods: The aim of this study was to assess the efficacy of PurastatÕ
in reducing the use of intraprocedural heat therapy during ESD.
This was a randomised controlled trial conducted in a tertiary referral centre
between May 2016 to April 2018. Patients undergoing ESD in the oesophagus or
colorectum were randomised in equal proportions to receive PurastatÕ as the
primary haemostat during intraprocedural bleeding (intervention) or heat therapy (control). Patients in the PurastatÕ arm were not excluded from heat therapy
treatment when required to achieve haemostasis. The primary endpoint was the
reduction in the amount of heat therapy required for intraprocedural haemostasis between PurastatÕ and control groups.
Results: 100 patients were recruited to the study. There were 2 withdrawals (ESD
aborted) and 7 had no bleeds. An intention to treat analysis was performed on 91
patients (see table).

Introduction: Intravenous (IV) use of CT-P13, an infliximab biosimilar, has
resulted in comparable efficacy, safety and immunogenicity as innovator infliximab in various indications including Crohn’s disease (CD)1 and rheumatoid
arthritis (RA)2. A subcutaneous (SC) formulation of CT-P13 is developed to
provide patients with opportunities for self-injection, thereby enhancing convenience and flexibility in treatment.
Aims and Methods: This work aimed to investigate immunogenicity by post-hoc
analysis of 2 randomised controlled trials comparing pharmacokinetics of CTP13 IV and CT-P13 SC. Patients with active CD (Crohn’s Disease Activity Index
[CDAI] score of 220–450) and RA (presence of 6 or more swollen and tender
joints [of 28 assessed], and serum C-reactive protein [CRP] concentration 40.6
mg/dL) were treated with CT-P13 IV at Weeks 0 and 2. At Week 6, patients were
randomised for continuation with IV or SC administration. The IV cohorts
received CT-P13 IV (5 mg/kg for CD and 3 mg/kg for RA) every 8 weeks and
the SC cohorts were treated with CT-P13 SC (120, 180 and 240 mg for CD and
90, 120, 180 mg for RA) every 2 weeks up to Week 30. Trough serum concentrations (Ctrough) were assessed at Weeks 6, 14 and 22 for IV and Weeks 6, 8, 10, 14,
22, 24, 26 and 28 for SC. Target exposure level was considered as 5 mg/mL for
CD3,4 and 1 mg/mL for RA5,6. Anti-drug antibody (ADA) was assessed before
study drug administration at Weeks 0, 6, 14, 22 and 30 by a drug-sensitive,
enzyme-linked immunosorbent assay (ELISA).
Results: In total, 92 CD (n ¼ 44) and RA (n ¼ 48) patients were randomised at
Week 6 to IV (CD: n ¼ 13, RA: n ¼ 13) or SC (CD: n ¼ 31, RA: n ¼ 35). Among
CD patients, immunomodulators (azathioprine, 6-mercaptopurine or methotrexate) were used at Week 6 by 9 (69.2%) and 15 (48.4%) patients in IV and SC
cohorts, respectively. All RA patients used methotrexate as concomitant medication throughout the study. Efficacy results in each indication (CDAI-70 responder rate for CD and EULAR [CRP] responder rate for RA) were comparable
between the IV and SC cohorts. Systemic safety profiles observed from CT-P13
SC after randomisation were also comparable to those of IV. A sub-therapeutic
Ctrough level below target exposure was detected at least once in 23 (92.0%) and 9
(14.1%) patients in IV and SC cohorts, respectively. ADA were detected at least
once in 16 (64.0%) versus 11 (18.1%) of patients in the IV and SC cohorts
(p 5 0.0001), respectively.

\[\text{Efficacy, Compliance, and immunogenicity among CD and RA patients} \]

Conclusion: After initial loading two doses of infliximab IV, patients subsequently receiving biweekly maintenance treatment with injections of CT-P13 SC achieve more stable steady state therapeutic levels of infliximab and have lower rate of anti-infliximab antibodies compared with patients receiving continued IV treatment. Further work to corroborate these findings is ongoing.

Introduction: Primary sclerosing cholangitis (PSC) is a chronic cholestatic biliary disease of unknown etiology, which increases the risk of developing cholangiocarcinoma (CCA). Currently, PSC patients frequently (80%) present inflammatory bowel disease, mainly ulcerative colitis (UC) (PSC-UC). Therefore, we propose serum extracellular vesicles (EVs) as a novel biomarker for the differential diagnosis of PSC and UC.

Aims and Methods: The aim of this study was to investigate the usefulness of protein biomarkers in serum EVs for the differential diagnosis of PSC-UC and UC patients, which could help in the early diagnosis of PSC in UC patients.

Methods: Serum EVs were isolated from PSC-UC (n = 21), UC (n = 64), and healthy individuals (n = 62) using ultracentrifugation/filtration methods. EV characterization was performed by transmission electron microscopy (TEM), nanoparticle tracking analysis (NTA) and immunoblot. The proteome of EVs was analyzed by mass spectrometry-based proteomics.

Results: Serum EVs showed round morphology by TEM, similar size (180 nm in diameter by NTA) and markers (CD9, CD63 and CD81 by immunoblotting) consistent with exosomes and small-size microvesicles. The proteomic profiles of serum EVs revealed 45 proteins to be differentially expressed in UC vs. controls, 66 in PSC-UC vs. UC patients with high diagnostic performance(sensitivity and specificity). In particular, proteins such as Aminoepinpeptidase N (AMPN), Polymeric immunoglobulin receptor (PIGR), G-protein coupled receptor family C group 5 member C (GPC5C) and Panethinease (VNN1) were exclusively upregulated (p < 0.05) in PSC-UC patients compared to UC and healthy controls. In contrast, proteins such as Complement factor I (CF1A), Ficolin-2 (FCN2) and Fibronectin (FCN1) were downregulated (p < 0.05) in PSC-UC patients compared to UC and healthy controls.

Conclusion: Proteomic signatures found in serum EVs of PSC-UC and UC patients show potential as non-invasive tools for diagnosis and follow-up.

Aims and Methods: The 52-week data from the phase 2, randomised, double-blind CELEST study (M13-740; NCT02365649) were analysed for long-term effects of 4 UPA regimens on PROs. All patients who completed the 16-week induction period were re-randomised 1:1:1 into an Extension Phase to receive UPA 3 mg twice daily (BID), 12 mg BID or 24 mg daily (QD) for 36 weeks. The 24 mg QD arm was later stopped and a 6 mg BID arm was initiated to evaluate an intermediate maintenance dose. Patients completed the Inflammatory Bowel Disease Questionnaire (IBDQ), EuroQol (EQ-5D) and Work Productivity and Activity Impairment (WPAI) PROs at baseline, week 16, and week 22. Outcomes at week 52 for patients who received UPA induction therapy and achieved clinical response at week 16 were assessed. Percentages of patients who achieved IBDQ response (defined as minimum clinically important differences (MCID) ≥16-point increase in IBDQ score from baseline) and who achieved IBDQ remission (IBDQ score ≥170) at week 52 were determined using non-responder imputation (NRI). Changes from baseline to week 52 were calculated using observed cases and analysis of covariance for IBDQ score, EQ-5D visual analogue score (VAS) and WPAI.

Results: Among 220 patients enrolled in CELEST, 180 were re-randomized into the Extension Phase. Of these, 153 patients received UPA induction therapy, of whom 94 achieved clinical response at week 16. Among week-16 clinical responders, a greater proportion of patients in the BID dose groups attained IBDQ response (43.8% vs 78.6%) and achieved IBDQ remission (43.8% vs 50.0%) at week 52 than those in the 24mg QD dose group (Table). Dose-related improvements in mean IBDQ scores (range 43-71) and EQ-5D VAS (range 18-36) were observed in the 3mg, 6mg and 12mg BID dose groups at week 52. At week 52, improvements in WPAI including reduction of activity impairment (26-42%) and work impairment (23-38%) were numerically greater for the BID dose groups.

Aims and Methods: Long-term follow-up data was retrospectively collected for patients who participated in the LIRIC trial; a multicenter, randomized controlled trial that compared laparoscopic ICR with IFX induction and maintenance therapy for adult patients with non-stricturing and immunomodulator refractory ileocecal Crohn’s disease (≥20cm). Primary outcome was the time to therapeutic intervention defined by the initiation or modification of medical therapy or surgery for disease flare or intolerance to treatment. Time to intervention was analyzed by Kaplan-Meier survival analysis. Potential predictive factors were defined a priori, identified through Cox proportional hazards regression analysis and expressed as hazard ratio (HR) [95% CI]. Tissue samples were taken from the surgical specimen (M0) and at time of recurrence (M1). The presence of mucosa-associated Enterobacteriaceae on the surgical specimen was an independent risk factor for severe post-operative recurrence of Crohn’s disease. Thus, the detection of AIEC at the time of surgery appears essential to adapt the postoperative treatment.

Introduction: The majority of patients with ileal Crohn’s disease (CD) undergo at least one intestinal resection during the course of their disease. Postoperative recurrence is a major issue, as up to 70% of them develop new lesions in their colorectal stump within 1 year of surgery. We aim to determine whether the presence of adherent and invasive Escherichia coli (AIEC) bacteria at the time of surgery was associated with endoscopic post-operative recurrence at 6 months.

Aims and Methods: The REMIND group (9 centers) has established a homogeneous, prospective, multicenter cohort (POP-REMIND) of operated CD patients. Tissue samples were taken from the surgical specimen (M0) and at endoscopy (M6), and stored centrally in a biobank. The inclusion criteria were: age ≥18 years, ileal or ileocecal CD requiring intestinal resection. Post-operative treatment was prescribed according to a standardized algorithm. Clinical outcome, therapeutic, biological and endoscopic data (Rutgeerts score) were collected 6 months after surgery. Clinical factors (demographic variables, phenotypic and postoperative treatments) associated with endoscopic recurrence were investigated by univariate and logistic regressions. The search for mucosa-associated E. coli bacteria was carried out by culturing on Drigalski medium, and adherent-invasive characteristics of E. coli was performed using hnt-407 cells, and survival within THP-1 macrophages.

Results: The presence of mucosa-associated E. coli strains was determined on the surgical specimen in 241 patients; 110 harbored mucosa-associated E. coli (45.6%). The presence of mucosa-associated E. coli on the surgical specimen was not correlated with age, disease duration, smoking, previous surgical resection, or corticosteroid use. In the IFX group (HR 0.21, 3e-8, 0.58). The presence of mucosa-associated E. coli on the surgical specimen was associated with increase risk of endoscopic post-operative recurrence (defined as Rutgeerts scores ≥12, 13 and ≥14; p = 0.01). Towards the endoscopic post-operative recurrence of Crohn’s disease, thus the detection of AIEC at the time of surgery appears essential to adapt the postoperative treatment.

OP240 MOLECULAR PROFILING OF ULCERATIVE COLITIS PATIENTS FROM THE TURANDOT TRIAL UNCOVERS NOVEL PHARMACODYNAMIC AND CLINICAL EFFICACY BIOMARKERS AND A MECHANISTIC RATIONAL FOR A NON-MONOTONIC DOSE RESPONSE
1Fizer Inc., Precision Medicine, Cambridge, United States
2Fizer Inc., Cambridge, United States
3Fizer Inc., Cambridge, United States

Introduction: FPPS-4765 (SHP647) is a human anti-mucosal addressin cell adhesion molecule-1 (MAdCAM-1) IgG monoclonal antibody that decreases intestinal inflammation through inhibition of MAdCAM-1-dependent lymphocyte recruitment. A phase 2 study (NCT 01602255), in patients with moderate to severe, active ulcerative colitis in the TURANDOT study showed the therapeutic efficacy of FFPS-476579 in a non-monotonic dose responsive manner, with the improved response in 225 mg dose cohort demonstrating greater efficacy than the highest 225 mg dose cohort1.

Aims and Methods: We aimed to define novel pharmacodynamic and efficacy biomarkers and to elucidate potential mechanisms underlying the observed non-monomeric dose response.

Transcriptome (RNA seq), protein (Olink), and immunohistochemistry (IHC) data were generated from the peripheral blood and intestinal biopsies of 310 patients from this phase 2 trial.

Results: Compared to the placebo group, C-C Motif Chemokine Receptor 9 (CCR9) gene expression demonstrated a 1.2, 2.0, 3.0 and 2.5-fold increase in the 7.5 mg, 22.5mg, 75mg, and 225mg cohorts, respectively (p = 0.21, 3e-8, 7.5e-18 and 1.8e-12) in peripheral blood, while in inflamed intestinal tissue, it demonstrated a 0.3, 0.4, 0.5 and 0.5-fold decrease in the 7.5 mg, 22.5mg, 75mg and 225mg cohorts, respectively (p = 0.046, 0.007, 0.0051, 0.028). Osteoclast M (OSM) gene or protein expression in peripheral blood or intestinal tissue demonstrated a 0.2 to 0.9-fold decrease among patients who showed efficacy (response, remission, or mucosal healing, p = 0.01 to 2.6e-8). Compared to the placebo group, intestinal T regulatory cells measured by IHC demonstrated a 0.2 to 0.9-fold decrease among patients who showed efficacy (response, remission, or mucosal healing, p = 0.01 to 2.6e-8).

Conclusion: These results reveal CCR9 and OSM as pharmacodynamic and efficacy biomarkers, respectively. Furthermore, the increased number of regulatory cells in the intestinal cohort at 225 mg dose cohort could suggest a greater sensitivity for T effector versus T regulatory cells to FFPS-4765-mediated blockade, implicating a potential mechanistic rationale for the observed non-monotonic efficacy response. Taken together, these findings may have significant implications for our understanding of UC disease pathophysiology and the development of future therapeutic approaches.

Introduction: Macrophages contribute to fibrosis through the release of different mediators and the pattern of secretion may vary according to their phenotype. Strong evidence identifies the Wnt signalling pathway as an emerging modulator of fibrosis. We have recently reported differences in the Wnt signalling pathway in surgical resections from Crohn’s disease patients presenting a strictureing (B2) or a non-stricturing (B3) behavior (1).

Aims and Methods: The aim of the present study is to analyze the pattern of expression of macrophages and the expression of Wnt ligands in surgical resections from Crohn’s disease (CD, n = 43) patients with different disease behavior. CD patients were categorized according to Montreal classification (B2 or B3) and an unaffected mucosa of patients with colorectal cancer was used as control. mRNA was isolated and the expression of macrophage markers, pro-inflammatory cytokines and Wnt2b was analyzed by RT-PCR (Gene-b-actin) mRNA expression; fold induction vs control group). The number of macrophages positive for the different markers (CD206, CD68, CD16 and CD61) was analysed by flow cytometry. Human peripheral blood mononuclear cells (PBMCs) were isolated from healthy donors and treated with secretomies from control, B2 or B3 surgical resections for 48 hours. mRNA from PBMCs was isolated and the expression of macrophage markers and Wnt2b was determined. Results are expressed by mean ± SEM (n≥5). Statistical analysis was performed by ANOVA + Newman-Keuls test. Correlations between data were analysed using Pearson’s correlation coefficient (p<0.05).

Results: The expression of pro-inflammatory cytokines, IL-1b and IL-6 and Wnt2b was significantly higher in intestinal samples from B3 CD patients (8.9±2.0, 8.7±1.8 and 2.3±0.4 respectively) than in controls (2.3±0.4, 2.4±0.6 and 1.1±0.1 respectively) or B2 CD patients (3.0±1.0, 3.9±0.8 and 0.7±0.1 respectively). The number of CD16 or CD68 positive macrophages was significantly higher in intestinal tissue from B3 CD patients (69.7±24.4% and 88.8±18.4%, respectively) than in that from B2 CD patients (56.12±5.8% and 30.58±10.9%, respectively). A high percentage of CD16 positive macrophages were also positive for Wnt2b in intestinal tissue from B3 CD patients (24.7±8.8%). A significant and positive correlation between WNT2b and CD16 (r=0.8, p=0.001) or CD68 (r=0.7, p=0.001) as well as CD16+ cells and CD61+ cells (r=0.7, p=0.002) was detected in intestinal tissue from B3 CD patients. The mRNA expression of CD16, CD68 and WNT2b was significantly higher in PBMCs treated with B3-secretomes (138.6±20.9, 33.8±0.0 and 12±3.2, respectively) than in those treated with B2- (3.3±1.8, 3.3±1.8 and 3.3±1.8, respectively) or control (1.2±0.5, 1.2±0.5 and 1.2±0.5, respectively) secretomes.

Conclusion: A pro-inflammatory/profibrotic macrophage phenotype may act as a source of Wnt2b in intestinal tissue from Crohn’s disease patients with a penetrating (B3) behavior.

A. Dunlop1, R. Arasaradnam1 showed the proportion presenting at Dukes A \( \equiv 6.9–8.5 \). Cancer stage at diagnosis was reported in 28.5% of papers. Pooled data weighting mean was calculated with a cancer conversion rate of 7.7% (95% CI 36.7% and 6.6% respectively1. The results provoke a reconsideration of the benefits of the TWW pathway for CR screening. Recal-evaluation of the criteria needs consideration with focus on symptoms with higher positive predictive value (PPV) in cancer.

Notes:

1. First-time invitees, 57,936 second-time invitees with a previous FIT cut-off level to increase the PPV and to alleviate the colonoscopy capacity. This study presents the impact of the increased FIT cut-off level on the results of the second round of the CRC screening program.

Aim: To investigate the impact of increasing the cut-off level on participation and yield in the second round.

Methods:

We present outcomes of the Dutch national CRC screening program in 2016. The target population for this year consisted of 3 groups of individuals: first-time invitees; second-time invitees that had been invited to FIT at a cut-off level of 15 µg Hb/g feces in 2014; and second-time invitees invited to a FIT at a cut-off level of 47 µg Hb/g feces in 2014. All participants in 2016 underwent screening with a 47 µg Hb/g feces FIT cut-off level. The FIT positivity rate and PPV for detecting CRC and/or Advanced Adenoma (AA) among FIT positive participants was compared between the three groups of individuals. Data were collected from Screen-IT, the national screening database covering the whole Dutch CRC screening program from selection of individuals for invitation to the colonoscopy and pathology reports.

Results:

A total of 1,497,591 individuals were invited for FIT in 2016: 1,038,998 first-time invitees, 57,936 second-time invitees with a previous 15 µg Hb/g feces cut-off level and 400,657 second-time invitees with a previous 47 µg Hb/g feces cut-off level (Table). Participation was high in both first- and second-time invitees: 71.8% and 76.2% respectively. As expected, FIT positivity was highest among first-time invitees (6.0%, 95%CI: 5.9-6.1). In second-time invitees, positivity rate was lower in those previously invited for a FIT with cut-off of 15 µg Hb/g feces (3.3%, 95%CI: 3.1-3.5), compared to those previously invited for a FIT with cut-off of 47 µg Hb/g feces (4.3%, 95%CI: 4.3-4.4). Results for detection rates and PPV showed a similar pattern (Table).

Conclusion:

Participation in the Dutch CRC screening program remains the highest in the world. The increase in FIT cut-off level in 2014 has not jeopardized participation. As expected, an increased FIT cut-off level in the first screening round resulted in relatively more positive FIT results and higher PPV the second round of the CRC screening program.
in the subsequent screening round. This suggests that most of the missed findings due to use of an increased FIT cut-off level are detected in the subsequent round, emphasizing the importance of repeated screening, especially within screening settings with high cut-off levels.

Introduction: Organized programs for colorectal cancer (CRC) screening have been associated with a substantial degree of CRC prevention in terms of its incidence and mortality. However, these programs demand a high burden of medical and economic resources. The 2 preferred screening methods are faecal immunochromatographic test (FIT) and primary colonoscopy. Our aim was to perform a cost-utility analysis between these 2 tests in an European setting.

Aims and Methods: A Markov cost-utility analysis was performed for the Portuguese population from a societal perspective comparing FIT or colonoscopy screening versus non-screening. Clinical data and utilities were collected from a systematic review and costs from published national data. Population was screened from 50 to 74 years-old by biennial FIT or colonscopy every 10 years and efficacy was evaluated in quality-adjusted life years (QALY). For the base case scenario, FIT cost was €3, with 50% acceptance, sensitivity 70% and specificity 95%; colonoscopy cost was €397 with 38% acceptance. An annual discount of 3% was used and the threshold was set at €39,760/QALY. The primary outcomes were the cost-effectiveness ratio (ICER), deterministic and probabilistic sensitivity analysis was done and colonoscopy burden was addressed according to the screening option.

Results: Biennial FIT screening and primary colonoscopy every 10 years screening resulted in a degree of CRC incidence and mortality prevention of 30% and 30%, and 38% and 38%, respectively. This translated in an incremental utility of 0.00157 QALY and 0.00185 QALY, as compared with no screening. The overall cost was €17.9 for FIT and €199.4 for colonoscopy, resulting in an additional cost of €10 and €191 vs. no screening, respectively. At cost-effectiveness analysis, FIT was the most cost-effective option providing an ICER of €6,383/QALY while colonoscopy every 10 years provided an ICER of €103,633/QALY. FIT screening was the most cost-effective option in 90% of simulations in sensitivity analysis and colonoscopy would have to increase 1.3% for a FIT program (26,000 colonoscopies/year, million screened) or 31% for a colonoscopy programme (48,000 colonoscopies/year, million screened).

Conclusion: Biennial FIT is a more suitable choice compared to primary colonoscopy screening resulting in a more rational exploitation of the limited endoscopic capacity. This further supports the progressive implementation of FIT-based programs in Europe.

Introduction: The fast-track colonoscopy program to detect patients with colorectal cancer (CRC) based on high-risk symptoms is associated with low sensitivity and specificity.

Aims and Methods: Define a predictive score of advanced colonic neoplasia (ACN) in symptomatic patients with indication of a fast-track colonoscopy.

All the patients referred for colonoscopy with fast-track indication were evaluated. We performed a retrospective analysis of patients included in the faecal immunological occult haemoglobin test (FIT) (samples) considering positive > 4 µg Hb/g faeces and a face-to-face survey to register clinical variables of interest. The main outcome was ACN defined as CRC or advanced adenoma (> 1 cm or high-grade dysplasia or villous component). The overall maximum faecal haemoglobin (MAXFIT) value, which maximizes the probability of ACN through the assessment of the diagnostic odds ratio (OR) was calculated, and was 11 µg Hb/g faeces. We assumed 3 categories for the MAXFIT variable: < 4, > 4 to 11, > 11 µg Hb/g faeces. A minimum sample size of 600 individuals was calculated for each phase of the study: Phase 1 (derivation cohort) and Phase 2 (validation cohort). A Bayesian logistic regression analysis using R software was performed to derive a predictive score and stratify the risk of ACN.

Results: 1495 patients were included (Phase 1 = 2). Differences were found between the derivation and the validation cohort in the variables related to the FIT (colorectal cancer screening resulted in a more rational exploitation of the faecal immunochemical test (FIT) (samples) considering positive > 4 µg Hb/g faeces and a face-to-face survey to register clinical variables of interest. The main outcome was ACN defined as CRC or advanced adenoma (> 1 cm or high-grade dysplasia or villous component). The overall maximum faecal haemoglobin (MAXFIT) value, which maximizes the probability of ACN through the assessment of the diagnostic odds ratio (OR) was calculated, and was 11 µg Hb/g faeces. We assumed 3 categories for the MAXFIT variable: < 4, > 4 to 11, > 11 µg Hb/g faeces. A minimum sample size of 600 individuals was calculated for each phase of the study: Phase 1 (derivation cohort) and Phase 2 (validation cohort). A Bayesian logistic regression analysis using R software was performed to derive a predictive score and stratify the risk of ACN.

Conclusion: A scoring system was derived and validated to prioritize fast-track colonoscopies according to risk, which was shown to be efficient, simple and robust.

Introduction: Post-Colonoscopy Colorectal Cancer (PCCRC) rate is a key quality indicator in colorectal screening. The Word Endoscopy Organization has reached consensus agreement to use one method for calculating 3-year PCCRC rates (termed PCCRC-3y) to enable international benchmarking of rates (1). This methodology, used previously by Morris et al (2), showed a PCCRC-3y rate of 8.6% across the English National Health Service (NHS) from 2001-2007(2) with a rate of 7.3% in 2007. This study aimed to determine the rate of PCCRC-3y in the English NHS Bowel Cancer Screening Programme (BCSP).

Aim and Methods: Data from each colonoscopy in the BCSP is entered into a national database, the Bowel Cancer Screening System. All colorectal adenocarcinomas, within and outside the BCSP, are validated and registered by the National Cancer Registration and Analysis Service. This retrospective observational study interrogated these databases to identify BCSP colorectal cancers and detect colorectal cancers within 6 months (true positive colonoscopies) and those BCSP colonoscopies in patients who subsequently developed a colorectal cancer 6 months – 3 years after the colonoscopy (false negatives) between 2006 and 2013.

Results: Of the 200 PCCRCs, 115 were detected at a subsequent BCSP procedure and 85 detected outside the BCSP.
2. Despite the high quality of colonoscopy in the BCSP, PCCRCs still occur, showing the importance of vigilance during all colonoscopies.
3. Diagnosis of >2000 colorectal cancers (true positive colonoscopies) each year indicates there is an adequate sample size for annual reporting of PCCRC-3y rate within the BCSP and comparison with PCCRC-yr rates in symptomatic services.

Introduction: After index colonoscopy patients with high-risk adenomas (> 2 polyps or ≥ 10 mm or high-grade dysplasia or villous or tubulovillous histology) should undergo surveillance colonoscopy after 3 years, patients with low-risk adenomas after 10 years. Although endoscopic screening reached high quality standards, interval cancers still occur in a significant number of patients and the underlying risk factors are poorly understood.

Aims and Methods: To evaluate if patients with high-risk adenomas are at increased risk for interval cancers. Screening colonoscopies performed between 1/2009 and 6/2015 within a nationwide quality assurance program were included. An interval cancer was defined as colorectal cancer diagnosed at least 6 months after screening colonoscopy and the scheduled time of surveillance colonoscopy.

Results: 146,894 colonoscopies were included (50.8% women, median age 60 years) of which 19% were classified as high risk. During a median follow up of 36 months, 572 interval cancers were identified. Patients with high-risk lesions had significantly higher incidence rates of interval cancers than those in the low-risk group (HR 1.77 [1.18–2.66]; p = 0.006). Other factors associated with interval cancer were older age (HR per 10 years 1.87 [1.52–2.29]; p < 0.001) and adenoma detection rate (HR 0.65 [0.44–0.95]; p = 0.025). Interestingly, there was no association with female sex.

Conclusion: High-risk lesions are a stronger predictor for the occurrence of interval cancer than poor adenoma detection rate. In contrast to previous studies there was no association with female sex.

Introduction: Detection of gastric cancer is difficult even for well-trained endoscopists, therefore machine learning is expected to be useful for reducing misdiagnosis and interobserver variability in endoscopic diagnosis. Dramatic changes in detection accuracy in machine learning have been occurring since the availability of the utility of convolutional neural network (CNN). Although many results have been reported, there are relatively few effective methods to automatically detect early gastric cancer with small morphological features, which implies that automatic detection methods can be extremely difficult to construct. Additionally, it is well-known that CNN-based methods require the learning about each normal structure and benign lesion, which will surely reduce the ability of AI to detect esophageal cancer including squamous cell carcinoma (SCC) and adenocarcinoma.

Aims and Methods: We collected 8428 training images of esophageal cancer lesions that were histologically proven to be SCC or adenocarcinoma in 384 patients in Cancer Institute Hospital, Tokyo, Japan from 2014 to 2017. The training esophageal cancer image included 397 lesions of esophageal SCCs (SCCs) which consisted of 332 lesions of superficial cancer and 65 lesions of advanced cancer. A total of 32 lesions of esophageal adenocarcinomas (EACs) were also included for training and consisted of 19 lesions of superficial cancers and 13 lesions of advanced cancers. With these training images, we developed deep learning through convolutional neural networks (CNNs). We also prepared 1118 test images in 47 patients with 49 esophageal cancers, including 41 SCCs and 8 EACs (169 images of esophageal cancer and 376 images without cancer), and 50 patients without esophageal cancer (573 images of the non-cancerous part of the esophagus) to evaluate the diagnostic accuracy. All cases of esophageal cancer were confirmed to have no other cancer using WLI, NBI, iodine staining, and follow-up endoscopy after the treatment.

Results: The CNN took 27 seconds to analyze 1118 test images and correctly detected esophageal cancer cases with a sensitivity of 98% (48/49). CNN could detect all 7 small cancer lesions less than 10 mm in size. In contrast the CNN misdetect 42 non-cancerous lesions, which caused low positive predictive value (54%). However, the PPV of NBI with magnification was reported to be 45% in experienced endoscopists and 35% in less experienced endoscopists, which was not so different from our outcomes. The misdiagnosed lesions included scars of esophagitis, small size endoscopic images were successfully done with showing detected cancers area as pseudo colored heatmap, and detection success was accomplished in a total of 106 images (82.8%) out of 128 cancer images. Conversely, a total of 491 identified (40.8%) out of 698 normal images were misdetect. The processing time was 4 ms per image, except for the time required to input/output the image.

Conclusion: Our preliminary CNN-based prediction scheme achieved high accuracy of early gastric cancer detection from the small amount of learning datasets. Automatic detection of early gastric cancer may offer sufficient assistance to endoscopists in decision making.

Disclosure: Nothing to disclose
Conclusion: Percentage of recognized neoplastic images where the algorithm detected the soft spot and sweet spot; 3) Red-flag indication: Percentage of recognized neoplastic images where the algorithm recognized the location of the neoplastic area and a ‘red-flag’ indication of only the most suspicious part of the neoplastic area. These results are promising and show feasibility of computer-aided detection as a red-flag detection technique in BE surveillance. Future steps of early BE neoplasia, thereby improving efficacy of BE surveillance. Recently, several deep learning techniques using Transfer Learning in Convolutional Neural Networks (CNNs) have shown promising results in other fields. CAD systems using deep learning techniques allow for faster execution time than the conventional clinically inspired algorithms, which will be essential for real-time operation. The aim of this study was to evaluate feasibility of a deep learning algorithm for detection of BE neoplasia using high-quality endoscopic images. Aims and Methods: Endoscopic overview images of 40 subtle early neoplastic BE lesions and 20 non-neoplastic BE patients were prospectively collected in White Light Endoscopy (WLE) in three tertiary referral centers. To establish a ground truth for detection and delineation, 6 international BE experts delineated all neoplastic images using a proprietary online delineation module. The area with at least 1 expert delineation was labelled as the soft spot. Positive samples were extracted from the sweet spot of the neoplastic images, while negative samples were taken from the area outside of the soft spot and from the NDBE images. The deep learning algorithm was trained using transfer learning on a ResNet50 model pre-trained on ImageNet. The images were divided in blocks of 128 x 128 pixels that were used as input to the CNN. Based on their location, each image block was then classified as neoplastic or non-neoplastic separately and aggregated to obtain a segmentation mask. For each detected neoplastic image, the algorithm produced 2 separate delineations: A complete delineation of the neoplastic area and a ‘red-flag’ indication of only the most suspicious part of the lesion. Outcome parameters: 1) Detection scores: Diagnostic accuracy of the algorithm per image in terms of accuracy, sensitivity, specificity, NPV and PPV; 2) Localization scores: Percentage of recognized neoplastic images where the delineation of the algorithm detected the soft spot and sweet spot; 3) Red-flag indication: Percentage of recognized neoplastic images where the algorithm red-flagged the soft spot and sweet spot. Performance was evaluated using 4-fold cross-validation. Results: Accuracy, sensitivity, specificity, PPV, NPV for detection per image were 92%, 95%, 85%, 93% and 90%, respectively. On the detected neoplastic images, the algorithm identified both the soft- and sweet spot to be neoplastic in all cases (100%). On these images the algorithm furthermore red-flagged the soft spot and sweet spot to be neoplastic in 97% and 87%, respectively. Conclusion: Detection scores of the first version of this deep learning algorithm were high. On all detected images, the algorithm recognized the location of the neoplastic lesion. These results are promising and show feasibility of computer-aided detection of early neoplasia in BE surveillance. Future steps will focus on further development of the algorithm towards video- and real-time analyses.

Introduction: Clinically significant post-endoscopic bleeding (CSPEB) is the most common complication following colonoscopic endoscopic mucosal resection (EMR). Current prediction tools are based on peri-procedural patient and lesion characteristics and do not account for the post-EMR mucosal defect appearance. We hypothesized that CSPEB may be predicted by analyzing the morphometric characteristics of blood vessels within the post-EMR mucosal defect. Our aim was to create a tool that will allow real-time identification of high-risk patients, thereby benefit from prophylactic treatment and close follow-up. Aims and Methods: Patients from the Australian prospective EMR cohort (ACE) were assigned to 2 groups based on presence or absence of CSPEB. The groups were matched in a 1:1 ratio for the clinical variables known to be associated with CSPEB (Age, aspirin use, lesion location in the colon, lesion size, histological subtype and intraprocedural bleeding). Standard EMR was performed, detailed patient lesion and procedural characteristics were recorded and meticulous photo-documentation prior to, during and after the procedure was obtained. A telephone interview was conducted 14 days after the procedure as part of the ACE study protocol, to record adverse events. Computerized morphometric analysis was used to quantify various morphologic characteristics of the blood vessels within the post-EMR mucosal defect. Multivariate Discriminant Regression Analysis and neural network were used as prediction models. Results: Over the course of 6 years, until 2015, 1332 colonic lateral spreading lesions (LSL) >20 mm under EMR at Westmead Hospital Sydney were analyzed. On the trains of the ACE study, 88/1332 (6.6%) had CSPEB. 43 cases and 43 matched controls with high quality images of the post EMR mucosal defect were selected for the analysis (median lesion size 40 mm (IQR 30-51.25)). Of 30 blood vessel characteristics, 5 morphometric characteristics were independently associated with CSPEB (table 1). Discernant analysis using the 5 independent predictors yielded 86% sensitivity and 76.7% specificity in correctly identifying patients at risk of CSPEB. A Neural Network (NNET) classifier using same independent predictors was trained on data of 60 subjects (30 controls and 30 cases) and subsequently tested on 26 subjects (13 controls and 13 cases). Training and testing subjects were chosen by computer randomization. The validated NNET yielded an sensitivity of 100% and specificity of 76.9% for correctly identifying patients at risk of CSPEB. Conclusion: Morphological characteristics of blood vessels in post-EMR defects can be used to predict delayed bleeding following colonic EMR. Future applications may include real-time computerized image analysis of blood vessels, which may assist in clinical decision-making regarding high-risk patients.

Introduction: Recently the American Society for Gastrointestinal Endoscopy (ASGE) addressed the “reject and discard” strategy, which suggests that diminutive polyps can be rejected and discarded without submitting pathological assessment, when it is estimated not as adenomatos polyps with high confidence. This strategy can reduce the physician’s burden, complications caused by biopsies, and medical costs. However, endoscopists need specific training until they can precisely detect and classify colorectal polyps, and in this regard computer-assisted diagnose (CAD) system may be of help. Previous studies have suggested promising application of artificial intelligence (AI), using deep learning in object recognition.

Aims and Methods: We aimed to construct a CAD using deep learning method that can accurately identify and classify CP in stored colonoscopy images. A deep convolutional neural network (CNN) architecture called Single Shot MultiBox Detector was utilized to develop and validate the CAD system in the present study. We trained the CNN using 16,418 images: 4,752 of CP and 4,013 of normal colorectum, and subsequently validated the performance of the trained CNN in 7,077 colonoscopy images, including 1,172 CP images from 309 various types of CP. Diagnostic speed and yields for the detection and classification of CP were evaluated as a measure of performance of the trained CNN.

Results: The processing speed of the CNN was 20 ms per frame. The trained CNN identified 1,247 CP with a sensitivity of 92% and a positive predictive value (PPV) of 86%. Among the correctly detected polyps, 83% of the CP were accurately classified, and furthermore, 97% of adenomas were precisely identified.

Conclusion: Our CNN showed robust performance to detect and classify CP through colonoscopy images, highlighting its high potential for future application as a CAD system of CP during colonoscopy.

Disclosure: T. Tada and K. Aoyama are employed by AI Medical Service Inc.
Aims and Methods: The study was performed as randomized, cross-over trial. 12 healthy lean male subjects received an intragastric glucose (ig-gluc) load with or without intravenous (iv) exendin-39-39 (ex9-39; specific GLP-1 receptor antagonist). Functional magnetic resonance imaging was used to investigate the effect of endogenous GLP-1 on resting state functional connectivity (rsfC) between homeostatic and reward-related brain regions. Visual analogue scales were used to rate appetite-related sensations. Blood samples were collected for insulin and glucose measurements.

Results: The main findings can be summarized as follow: i) after iv-ex9-39/ig-gluc a significantly higher rsfC was found relative to ig-gluc between the hypothalamus and the left lateral orbitofrontal cortex (OFC) as well as the left amygdala (p<0.001, respectively); ii) after iv-ex9-39/ig-gluc a significantly higher rsfC was found relative to ig-gluc between the midbrain (VTA) and the right caudate nucleus (p<0.001); iii) iv-gluc significantly decreased prospective food consumption and increased fullness sensations compared to the pre-infusion baseline (p=0.028 and p=0.019, respectively), these effects were not present in the iv-ex9-39/ig-gluc condition v) after iv-ex9-39/ig-gluc an attenuated increase in plasma glucose concentration was relative to ig-gluc (p=0.012).

Conclusion: In conclusion, this trial in healthy lean individuals indicates that glucose-induced endogenous GLP-1 release affects central regulation of appetite by modulating rsfC in homeostatic and reward-related brain regions in a GLP-1 receptor-mediated fashion.

**Contact E-Mail Address:** shibata200101545@yahoo.co.jp

**Introduction:** Endoscopic findings for patients with Ulcerative Colitis (UC) are important to evaluate the extent and severity of the disease, as well as to determine the management of UC. However, since endoscopic diagnosis is an observer-dependent method, a certain period of training time is necessary for endoscopists to acquire sufficient ability to accurately evaluate the inflammatory disease activity. Inter-observer variability is known to exist in endoscopic diagnosis. An image recognition system with artificial intelligence (AI) has great potential to support physicians' clinical practices by providing objective and specialist-level diagnoses in the field of gastrointestinal endoscopy (1), including in the diagnosis of UC.

**Aims and Methods:** In this study, we constructed a computer-assisted diagnosis (CAD) system with a convolutional neural network (CNN) and evaluated its performance with a large dataset of endoscopic images from UC patients. A retrospective review was performed of patients with UC who underwent colonoscopy at a single center in Japan from October 2006 to June 2017. A CNN-based CAD system, constructed based on GoogleLeNet architecture, was trained with 26,304 colonoscopy images from 841 UC patients that were tagged with both anatomical locations and Mayo endoscopic scores (Mayo 0, Mayo 1, and Mayo 2-3). The performance of the CNN to identify mucosal healing state (Mayo endoscopic score 0 or 1) was evaluated in an independent test set of 4,589 images from 117 UC patients using receiver operating characteristic (ROC) curves and calculating the area under the receiver operating characteristic curves (AUCs). Additionally, AUCs in each location of the colorectum (right-sided colon, left-sided colon, and rectum) were evaluated.

**Results:** Of the 4,589 images, 65% (1237 of 1890 images) of the Mayo 0 images, 56% (1295 of 2293 images) of the Mayo 1 images, and 51% (206 of 406 images) of the Mayo 2-3 images were correctly classified as each class of Mayo scores by the CNN-based CAD system. ROC curves of the CNN-based CAD system showed high performance with an AUCROC value of 0.95 to identify Mayo endoscopic score 0 or 1 vs. 2 or 3. The performance of the CNN was better in right-sided colon and left sided-colon than in rectum (AUCROC = 0.96, 0.97, and 0.88, respectively).

**Conclusion:** The CNN-based CAD system showed robust performance in identifying endoscopic inflammation severity in patients with UC, highlighting its capacity to support immature endoscopists and reduce inter-observer variability.

**Introduction:** Endogenous infusion of glucagon-like peptide-1 (GLP-1) triggers appetite responses and can affect brain activity in areas involved in the regulation of appetite, including hypothalamic and reward-related brain regions. In contrast, the physiological role of endogenous GLP-1 in the central regulation of appetite has hardly been investigated.

**Aims and Methods:** The study was performed as randomized, cross-over trial. 12 healthy lean male subjects received an intragastric glucose (ig-gluc) load with or without intravenous (iv) exendin-39-39 (ex9-39; specific GLP-1 receptor antagonist). Functional magnetic resonance imaging was used to investigate the effect of endogenous GLP-1 on resting state functional connectivity (rsfC) between homeostatic and reward-related brain regions. Visual analogue scales were used to rate appetite-related sensations. Blood samples were collected for insulin and glucose measurements.

**Results:** The main findings can be summarized as follow: i) after iv-ex9-39/ig-gluc a significantly higher rsfC was found relative to ig-gluc between the hypothalamus and the left lateral orbitofrontal cortex (OFC) as well as the left amygdala (p<0.001, respectively); ii) after iv-ex9-39/ig-gluc a significantly higher rsfC was found relative to ig-gluc between the midbrain (VTA) and the right caudate nucleus (p<0.001); iii) iv-gluc significantly decreased prospective food consumption and increased fullness sensations compared to the pre-infusion baseline (p=0.028 and p=0.019, respectively), these effects were not present in the iv-ex9-39/ig-gluc condition v) after iv-ex9-39/ig-gluc an attenuated increase in plasma glucose concentration was relative to ig-gluc (p=0.012).

**Introduction:** Morbid obesity is a worldwide major health problem that carries enormous socio-economic costs and a high incidence of comorbidities such as hypertension, diabetes mellitus (DM), and dyslipidemia. Bariatric surgery is the only proven effective treatment; however, treatment rates remain low, because of enormous socio-economic costs and a high incidence of comorbidities such as hypertension, diabetes mellitus (DM), and dyslipidemia. Bariatric surgery is the only proven effective treatment; however, treatment rates remain low, because of poor patient acceptance, high costs, and non-negligible risks of complications. Any alternative treatment that could cure, control or even improve the morbidity of obesity and related diseases would have a tremendous medical, social and economic impact. Endoscopic sleeve gastropasty (ESG) is an incisionless procedure suitable for widespread clinical adoption shown to be effective to induce weight loss up to 24 months in moderately obese patients. Currently, few data are available concerning the effects of ESG on comorbidities related to morbid obesity.

**Aims and Methods:** The aim of this study is to evaluate the impact of ESG on comorbidities (including obesity, diabetes mellitus, hypotension, hypertension, gastro-esophageal reflux, sleep apnea) at 6 months follow-up. Between October 2016 and April 2018, 92 patients underwent ESG in 2 expert centers. ESG was performed by the application of 4 to 6 full-thickness sutures using the OverStitch suturing platform. Patients mean % of excess weight loss (%EWL), clinical outcomes and medication use were assessed. Quality of life (QOL) was evaluated with the GQFLI and the BARQOS questionnaires.

**Results:** 24 patients (26%) had a mean follow-up of at least 6 months and 15 (62.5%) presented at least 1 comorbid condition at inclusion. At 6 months %EWL was 29.95±20.26 and 13 patients (86.6%), reduced (60%) or suspended (33.3%) pre-operative medications (p=0.001) (Table 1). No correlation was
found between weight loss and improvement or suspension of medications with those of the diabetic patients in whom a greater weight loss resulted in a reduction of oral antidiabetics or insulin use (Pearson 0.746, p = 0.04; Spearman 0.737, p = 0.03).

Mean GIQLI score improved from 105.4 ± 17.2 (p = 0.06) to 113.4 ± 16.84 and mean BAROS score from 9.0 ± 0.9 to 1.3 ± 1 (p = 0.03).

Conclusion: ESG is a safe and effective bariatric endoscopic procedure that resulted in a positive impact on both metabolic diseases and quality of life. Thus, ESG could provide a unique opportunity to reach a greater number of obese patients, earlier in their disease or at a younger age presenting with metabolic comorbid conditions. Larger studies are needed to confirm these preliminary encouraging results.

Introduction: The clinical management of Helicobacter Pylori (HP) infection in obese patients is complicated due to the lower eradication rates with standard therapeutic therapy. Body Mass Index (BMI) is an independent risk factor. Although the cause of this poor eradication remain to be elucidated, the physiological changes that obesity produce may lead to sub-therapeutic antibiotic concentrations and the current paradigm “one dose fits all” may be changed. The impact of these changes depends upon patient characteristics (degree obesity, underlying organ function) and the chemical properties of the antibiotic (hydrophilic or lipophilic). For most drugs, the interaction between drug pharmacokinetics/pharmacodynamics and BMI is complex and there is a lack of consensus formula that should be used for dosage calculation.

Aims and Methods: To evaluate the HP eradication of a tailored Quadruple Concomitant regimen based on body weight compared to standard Quadrupe Concomitant therapy in obese patients undergoing bariatric surgery. This prospective, open-label study included 104 obese patients undergoing bariatric surgery. Upper endoscopic HP assessment by histology and 14CO2 breath test were performed at baseline and the post-treatment status was assessed by C13 Urea Breath Test, 6-8 weeks after the end of therapy. All patients were treated 14 days with a Quadruple Concomitant therapy with a proton pump inhibitor, amoxicillin, clarithromycin, and metronidazole. These patients received a tailored regimen based on the body weight. Lipophilic antibiotics (metronidazole and clarithromycin) were adjusted according with the Total Body Weight until their maximal doses. Amoxicillin (hydrophilic drug) was adjusted with the Adjusted Body Weight (Ideal Body Weight according to the modified Devine formula and a weight correction factor of 0.3) until their maximal dose. Simultaneously, 53 obese patients, received the standard Quadrupe Concomitant therapy with a proton pump inhibitor BID, clarithromycin 500 mg BID, amoxicillin 1000 mg BID and metronidazole 500 mg BID.

Results: Per-protocol and intention-to-treatment eradication after the tailored body weight regimen were 90% (95% CI 77-96) and 86% (95% CI 73-93) whereas in the standard treatment obese group was 67% (per-protocol 95% CI 53-78) and 70% (95% CI 52-77) by intention-to-treat. HP eradication in obese patients with the tailored body weight regimen were significantly higher than the control obese group, p < 0.001 Per-protocol and p < 0.05 Intention-to-treatment. The distribution of age, gender, smoking and diabetes did not differ significantly between the 2 groups. 3 patients discontinued the treatment due to adverse events.

Conclusion: A tailored Quadruple Concomitant regimen based on body weight in obese patients undergoing bariatric surgery is significantly more effective than standard Quadruple Concomitant therapy. A tailored eradication treatment with the antibiotics adjusted according to the body weight could be considered as a new strategy for obese patients.

Introduction: The global population of elderly (>65 years) is increasing and will have a major impact on healthcare systems due to an increased incidence of age-related diseases. Gastrointestinal (GI) symptoms are common among the elderly and approximately 60% are estimated to be affected (3, 4). The elevated pharmaceutical load in elderly is of potential harm to the intestine and it may play an long-term role of non-steroid anti-inflammatory drugs (NSAID), commonly used for pain management among elderly, can cause gastric ulceration, enteropathy (5, 6) and increased intestinal permeability (7). A deteriorated barrier function is associated with increased psychological distress in elderly with GI symptoms (8), and many diseases of inflammatory character such as inflammatory bowel disease (9). We have previously shown that specific dietary fibres attenuate stress-induced hyperpermeability ex vivo in ileal tissues from patients with Crohn’s disease (9). However, the potential of dietary fibres to strengthen the intestinal barrier function in vivo in elderly individuals is, to our knowledge, not known.

Aims and Methods: We performed a placebo-controlled parallel clinical trial to investigate whether 6 weeks of oral supplementation of wheat-endosperm derived
OP260 PERCUTANEOUS TRANSESOPHAGEAL GASTROTUBING (PTEG) AS THE SUITABLE PROCEDURE FOR THE PATIENTS THAT PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) INSERTION IS CONTRAINDICATED

M. Murakami1, K. Nishino1, T. Okamoto1, S. Muakami1, K. Mori1, M. Kida2, W. Koizumi2
1 Kitasato University School of Medicine, Internal Medicine, Sagamihara, Japan
2 Murakami Memorial Hospital, Dept. of Internal Medicine, Saijo, Japan

Introduction: Percutaneous transesophageal gastrostomy (PTEG) was developed as an alternative to the gastrostomy tract for the patients that PEG insertion was contraindicated with conditions such as prior gastrectomy, gastric anterior wall malignancies, or massive ascites. PTEG will be an ideal method for tube feeding and decompression.

Aim of the Study: To evaluate the clinical usefulness of PTEG for the patients who need tube feeding or decompression from gastrointestinal tract. A rupture-free balloon (RFB) catheter is inserted into the upper esophagus. Percutaneous balloon puncture with a specialized needle is then performed through the left side of patient’s neck under ultrasonographic control. A guide wire is inserted through the needle into the RFB, followed by a dilator and guide wire is inserted through the needle into the RFB, followed by a dilator and after dilatation through the balloon. We perform PTEG in a total of 172 patients (109 men and 63 women, mean age 71.2 years) in whom PEG was not feasible. PTEG was performed for nutrition in 97 patients and for decompression in 75.

Results: Satisfactory results were achieved in all 172 patients. Median follow-up time for nutrition and 60.6 days for patients who received decompression. All patients were free from nasal tube prior insertion. 6 of 97 patients for nutrition were able to be freed from tube feeding due to PTEG tube feeding support, oral ingestion could be achieved in 44.0% and home care could be attained in 66.0% with decompression group patients.

Conclusion: PTEG is a useful procedure for the patients who are contraindicated to PEG. PTEG is an only procedure to be free from a nasal tube especially for the patients with carcinomatous peritonitis. PTEG is a suitable procedure for the patients having an eating disorder and/or the malignant disease as tubal feeding and palliative care.

Aims and Methods: The aim of our study was to study the effect of the genetic inhibition of Cyp D in the pancreatic ductal epithelial cells. Wild type (WT) and Cyp D knock out (KO) mouse pancreatic ducts were isolated by microdissection. Mitochondrial membrane potential (ΔΨm) was measured by confocal microscopy and pancreatic ductal HCO3⁻ secretion by microfluorometry. Functionally active mitochondria in the pancreatic ducts were detected by immunofluorescence microscopy using TOMM20 mitochondrial marker.

Results: The genetic knock out of cyclophilin D significantly reduced the loss of Cyp D–/–protected pancreatic ductal HCO3⁻ secretion by microfluorometry. Functionally active mitochondria in the pancreatic ducts were detected by immunofluorescence microscopy using TOMM20 mitochondrial marker.

Conclusion: Our results suggest that mitochondrial function has a central role in the function of PDEC presumably by providing ATP for fluid and ion secretion. On the other hand the opening of MPIT may be crucial in the bile acid induced toxicity offering a potential therapeutic target in AP.

Disclosure: Nothing to disclose
cross-species analysis, we compared the pericyte coverage in KPC mice in comparison to wild-type mice. To investigate the interactions between angiogenesis and neurogenesis in vitro, we developed a 3D heterotypic co-culture system with mouse dorsal root ganglia (DRG), PCa cells and pericytes, and determined the neurtile density of DRG neurons. In a transcriptomic analysis, we compared the transcriptional profile of pericytes that were stimulated with PCa cell supernatants and compared this to unstimulated pericytes.

Results: In human PCA tissues, PCV and PCl were increased around CD45+ microcapillaries when compared to NP (PCV and PCl were 23.4 ± 3.7%, p = 0.0048; 19.6 ± 2.2% vs. 21.6 ± 3.2%, p = 0.018). Similarly, PCV & PCl were higher around macrocapillaries-associated pericytes (αSMA+/CD31-stained areas), when compared to NP. In KrasG12D-based mouse PCA models, there was a very similar increase in the PCV and PCl in the BC, compared to the KPC model (p = 0.0105). There was no correlation between PCV, PCl and nerve density or neural invasion. In 3D co-cultures, DRG exhibited enhanced neurite density upon coculture with both PCa cells and pericytes. PCa-cell-stimulated pericytes upregulated the expression of multiple molecules in metabolic and pro-inflammatory pathways.

Conclusion: Increased pericyte coverage is one of the typical alterations in the PCA microenvironment. Activated pericytes also seem to contribute to PCA-associated neurogenesis.

Disclosure: This abstract has also been submitted for presentation at the 2018 meeting of the European Pancreatic Club.

Introduction: Type 1 autoimmune pancreatitis (AIP) is now accepted as a new clinical entity of pancreatic disorder that is characterized by diffuse irregular narrowing of the main pancreatic duct, lymphoplasmacytic infiltration with fibrosis, Th2-balanced inflammation, and high serum levels of IgG or IgG4. Since the fibroinflammatory process of AIP responds to immunosuppressants, abnormal immune systems are considered to be involved in the development of AIP. However, the investigation of the complex pathogenetic mechanisms underlying this disease remains to be elucidated.

Exosomes are small extracellular vesicles secreted by myriad of cell populations into body fluids, playing a pivotal role in cell-to-cell communications. These vesicles convey nucleic acids, including microRNA, and proteins derived from both PCA and pericytes. PCa-cell-stimulated pericytes upregulated the expression of multiple molecules in metabolic and pro-inflammatory pathways.

Conclusion: Increased pericyte coverage is one of the typical alterations in the PCA microenvironment. Activated pericytes also seem to contribute to PCA-associated neurogenesis.

Disclosure: This abstract has also been submitted for presentation at the 2018 meeting of the European Pancreatic Club.

**VC01 ENDOSCOPIC APPENDICEAL FECALITIS EXTRACTING BY NOTES TECHNIQUE**

L. Bing, P.-H. Zhou, Y.-S. Zhong
Zhejiang University Hospital. Fudan University. Endoscopy Center and Endoscopy Research Institute, Shanghai, China

Contact E-Mail Address: zhongyunshi@yahoo.com

Introduction: A 74-year-old man had a 2-weeks history of repeated right lower abdominal pain. Colonoscopy revealed a 10-mm subepithelial lesion near the appendiceal orifice. The lesion could be pushed by a biopsy forcep and was found to have in the KC, histioma. It was well defined and appeared heterogenous in endoscopic ultrasonography. Contrast-enhanced computed tomography showed a 8×10mm high density mass in the cecum. Chronic appendicitis caused by appendicealecalcal obstruction was suspected.

Methods: After ERAT failed, a endoscopic treatment was still requested by patient. Therefore, the endoscopic appendiceal fecalith extraction was attempted.

Results: First, along the market dots, the anal side mucosa of the lesion was incised using a flush-knife. Then, a metal clip with dental floss bited the incised mucosa, and another metal clip was used to fix the pull line to the opposite side of cecal wall. So, a pulley-like traction device was structured to expose the subepithelial layer. After the full-thickness resection of cecum and appendix, a fecalith was exposed in the appendix lumen and was taken out by a snare soon. After careful hemostasis, the cecum and appendix defect was closed by metallic clips partly, and the residual defect was unclosed to form a artificial fistula (arrows) from appendix to cecum for internal drainage. The patient experienced no procedure related adverse events.

Conclusion: This novel NOTES technique provides another choice for manage- ment of the subepithelial lesion-like appendiceal fecalitils.

Introduction: Small bowel diverticula are a rare cause of gastroduodenal (GI) bleeding. Their pathogenesis is still unclear and can be found in up to 1-2% of the general population. Although these lesions are usually asymptomatic, midgut bleeding from diverticulitis in the jejunum or ileum could lead to a life-threatening situation, warranting emergency invasive therapy and often abdominal surgery.

Aims and Methods: Our aim was to demonstrate the usefulness of the double-balloon enteroscope (DBE) in the setting of an acute, severe small bowel diverticular bleed. A 79-year-old woman with hypertension and type II diabetes mellitus was referred to our institution with melena and severe anaemia requiring urgent, repeat blood transfusions. Bi-directional conventional endoscopy did not reveal the cause of bleeding. Small bowel capsule endoscopy (SBCE) showed multiple diverticula within the jejunum and ileum. Emergency computed tomography (CT) mesenteric angiography demonstrated a faint ’blush’ at one of the jejunal lesions.

Results: Once the patient was haemodynamically stable, emergency antegrade DBE was performed under general anaesthesia (GA) in our main operating theatres. The enteroscope was inserted into the jejunum, approximately 1.5 meters post-pylorus. The culprit cause of the bleeding was identified within a large (5mm orifice) diverticulum, where a large, adherent, pulsating blood clot was seen. In the first instance, peri-lesion, quadrant injection of a total of 20mLs of adrenaline solution (1 in 10,000 dilution) was performed. The clot was then cautiously removed with a long endocolip to reveal the actively bleeding vessel which was then promptly clipped. A total of 3 clips were placed for effective haemostasis and a submucosal tattoo was placed adjacent to the bleeding point for future reference. The patient remained stable after the procedure and did not require any further blood transfusion.

Conclusion: DBE facilitated endotheraphy is a precise, safe and minimally invasive approach to the effective management of severe bleeding caused by small bowel diverticulitis.

Introduction: Incidental duodenal non-ampullary lesions are found at upper gastrointestinal (GI) endoscopy in 1-5% of cases. Endoscopic resection of duodenal lesions carries a higher risk of bleeding due to the rich vascularity and exposure to bile and pancreatic enzymes. The risk of perforation is also intrinsically increased due to the presence of the duodenal wall. In addition, endoscopic resection of fibrotic duodenal lesions can be extremely challenging (even in expert hands) and carries high failure and complication rates, often warranting extensive surgical management. To date, there is no widely accepted optimal management strategy for duodenal lesions and conservative management with endoscopic surveillance is frequently adopted. Although at diagnosis, duodenal adenomas are most often benign, they retain an intrinsic risk of malignant transformation.

Aims and Methods: Our aim was to use a novel, combined endoscopic approach for the management of an otherwise unresectable giant, fibrotic, circumferential lesion involving the whole duodenal bulb.

A 72-year-old woman with hypertension presented with anaemia and melena. An upper GI endoscopy revealed a 7 cm circumferential lesion (Paris 0-IIa, 0-IIb) laterally spreading tumour (LST) involving the entire duodenal bulb. Histopathological analysis of biopsies taken at another institution, were in keeping with a papillary adenoma with low-grade dysplasia, whereas the muscularis propria was excluded by endoscopic ultrasound (EUS).

Results: A first resection attempt through a combination of wide-field endoscopic mucosal resection (EMR) and saline-immersion therapeutic endoscopy (SITE) halted, but EMR techniques allowed only resection of up to 10% of the lesion, due to severe fibrosis. Delayed bleeding 24 hours post-resection was successfully treated endoscopically. 6 weeks later, a planned second attempt at endoscopic resection was performed under general anaesthesia. The lesion was initially injected with adrenaline solution (1 in 10,000 dilution). A combination of the use of a novel, non-thermal, automated-mechanical-suction-resection system with cold snaring allowed us to achieve 50% resection of the lesion in less than 2 hours. Mild, self-limiting, intra-procedural oozing did not require further endotherapy for immediate or delayed adverse events to occur.

Conclusion: The resection using the same technique is planned to be performed shortly.

VC04 UNDERWATER PANCREATOSCOPY THROUGH THE DUCT OF SANTORINE: DIRECT VISUAL GUIDED BIOPSIES OF AN INTESTINAL-TYPE IPMN

Introduction: Intraductal papillary mucinous neoplasms (IPMNs) of the pancreas are potentially malignant intraductal epithelial neoplasms that are grossly visible and are composed of mucin-producing columnar cells. The lesions show papillary proliferation, cyst formation, and varying degrees of cellular atypia [1,2]. IPMNs may involve the main pancreatic duct and/or the branch ducts, carrying a risk of malignancy from 15%-60% [3]. The approach to the diagnosis of pancreatic cystic neoplasms typically starts with cross-sectional imaging as abdominal MRI or CT-scan [4]. Endoscopic ultrasound with fine-needle aspiration can lead to the diagnosis or to assess for malignant features. Pancreatocscopy and intra-ductal ultrasonography can allow direct endoscopic visualization of the pancreatic ducts, and ductal lesions can be directly biopsied. In our case, the pancreatocscopy, allowed the diagnosis to be made before progression to invasive cancer and the subsequent surgery.

Buried bumper syndrome (BBS) is a rare, long-term complication of inflammation or in association with spastic motility disorders such as achalasia. Effective endoscopic therapy for thoracic diverticula is yet to be described.

**Aims and Methods:** This video describes 2 cases of the use of a novel technique of intraluminal submucosal myotomy (ISM) for patients with symptomatic epiphrenic diverticula associated with spastic oesophageal motility disorders.

**Results:** This video describes 2 cases showing the technique of ISM.

**Case 1:** 39-year-old female with a 2-year history of worsening dysphagia, chest and regurgitation of food. After a failed surgical diverticulotomy the patient was diagnosed with hypertensive peristalsis on manometry. She initially underwent a POEM procedure with some symptom resolution but developed dysphagia due to stenosis at the site of the diverticulum. An ISM was performed. The patient is symptom free 6 months later.

**Case 2:** 64-year-old female with a 12-month history of chest pain and regurgitation of food. Manometric assessment confirmed diffuse oesophageal spasm and diagnosis of BBS and abdominal computerised tomography confirmed this.

**Conclusion:** ISM is an effective and safe new novel technique for treatment of epiphrenic diverticula associated with spastic oesophageal motility disorders.

**Disclosure:** Nothing to disclose.

Introduction: Radiation proctitis (RP) is a complication occurring in 5% to 20% of patients undergoing pelvic radiotherapy (RT). Argon Plasma Coagulation (APC) is the endoscopic treatment of choice for CRP, as it is considered to be effective and well-tolerated.

Aims and Methods: 3 patients (74, 82 and 60 yrs) with a history of pelvic neoplasia underwent lower endoscopy that showed presence of haemorrhagic chronic radiation proctitis (RP). All 3 patients received treatment with rectal band ligation (RBL). We report 3 cases of patients with a history of pelvic neoplasia who developed RP following RT, who have been successfully treated with rectal band ligation (RBL).

Results: The procedures were well tolerated and no pain was referred during the RBL nor during the following days. 1 patient presented tenesmus, resolved by conservative treatment with topical drugs. During follow-up the 3 patients were asymptomatic and no further episodes of rectorrhagia were reported.

Conclusion: RBL is effective, safe and fast, and offers an alternative treatment for radiation proctitis, especially in the case of extensive disease.

Introduction: Neoplastic pancreatic cystic lesions are discovered with increasing frequency, with the most prevalent being the intraductal papillary mucinous neoplasm (IPMN). Most IPMNs will never evolve into malignancy, but because risk stratifying tools are lacking, the majority of cysts currently undergo redundant lifelong surveillance.

Aims and Methods: We aimed to develop a score chart to identify IPMN with low risk to progress and fulfill the resection criteria according to the 2012 international Fukuoka guidelines. We retrospectively reviewed the prospectively-managed database of three international academic institutions, containing patients with a pancreatic cystic lesion identified in the period 2003-2013. Patients were included if they had a presumed IPMN on imaging, without worrisome features or high-risk stigmata at baseline, as defined by the 2012 international Fukuoka guidelines, and were followed ≥12 months. Fulfilling resection criteria was

Abstract No: OP268

Table 1: Patient and cyst characteristics and final multivariable logistic regression model.
**Aims and Methods:** The study aimed to evaluate the occurrence of gastric neoplastic lesions and changes of OLGA/OLGIM scores in AG patients at 3-years endoscopic-histological follow-up. A total of 80 consecutive, newly diagnosed AG patients (77.5% F, median age 64.5 [29-87] years) followed-up 3 years after diagnosis were included. Each patient underwent gastroscopy with biopsies (Sydney System) at baseline and at 3 years follow-up. Among them, 25 (31.1%) were cured from H. pylori. At baseline OLGA scores 0, I, II, III, IV were observed in 6, 22 (27.5%), 43 (53.7%), 4 (5%), 0 patients, respectively. Extensive atrophy/intestinal metaplasia was present in 22 (26.3%) patients. At baseline 7.8% patients presented polyoid neoplastic lesions, all removed by snare polypectomy: 3 low-grade dysplasia (LGD) adenomas and 4 T1GC. The number of gastroscopies needed to be performed (NNS) to detect 1 case of gastric neoplastic lesion was expressed as the number of 3-years surveillance endoscopies by the number of detected neoplastic lesions.

**Results:** At 3-years follow-up 12 (7.5%) neoplastic lesions were detected: 12 (7.5%) LGD adenomas in 2 patients, 4 (5%) carcinoids in 4 patients (in 2 of them recurrent), no GC. The NNS was 13.3. OLGA and OLGIM scores were unchanged, increased and decreased in 58 (72.5%), 9 (11.3%) and 15 (18.8%), 13 (16.2%) and 16 (20%) patients, respectively.

The occurrence of gastric neoplastic lesions in patients with or without extensive atrophy/intestinal metaplasia was not different (p = 0.943 by chi-square test). Patients with extensive atrophy/intestinal metaplasia at baseline would have been considered eligible for surveillance, at 3-years follow-up only 1 LGD adenoma would have been detected, as the other neoplastic lesions 4 T1GC and the other LGD adenoma occurred in patients without extensive atrophy/intestinal metaplasia at baseline.

**Conclusion:** In AG patients, the 3-years endoscopic surveillance as proposed by MAPS seems satisfactory to early detect potential gastric neoplastic lesions. An increased OLGIM score in a low proportion of patients (10% and 18%). Extensive atrophy/intestinal metaplasia as eligibility criteria to offer surveillance in AG patients may be restrictive.

**Disclosure:** Nothing to disclose.

**References**
lymph node (LN) and distant metastasis did not differ between the groups. Overall, 5-year disease-free survival did not differ between the groups (88.6 vs. 93.8%; p = 0.259, 98.2 vs 100%; p = 0.484), but 5-year disease-free survival was lower in the observation group (73.5 vs 97.9%; p < 0.001). On multivariate analysis, presence of ulcer, large tumor size, tumor-positive lateral and vertical margins, lymphatic and venous invasion, additional surgical resection should be considered for the risk of residual tumor or LN metastasis.

OP272 LOWER RISK OF ATROPHIC GASTRITIS IN MALT LYMPHOMA DESPITE H. PYLORI INFECTION

S.M. Lee, E.H. Park, D.Y. Cheung
The Catholic University of Korea College of Medicine, Seoul, Korea (Republic of)

Contact E-Mail Address: adagio@catholic.ac.kr

Introduction: Atrophic gastritis and intestinal metaplasia are sequelae consequent of chronic H. pylori infection. H. pylori infection is a well-known risk factor for gastric adenocarcinoma and MALT lymphoma of the stomach. Atrophic gastritis and intestinal metaplasia increase the risk of gastric adenocarcinoma, and the relationship between gastric MALT lymphoma and atrophic gastritis-intestinal metaplasia has not been on the spot of interest. We here investigated the clinical characteristics of gastric MALT lymphoma and presence of atrophic gastritis and intestinal metaplasia.

Aims and Methods: Study was conducted by review of the electronic medical record of patients who were diagnosed with gastric MALT lymphoma at an academic institute, the Yeouido St. Mary’s Hospital, Seoul, Korea, from January 2001 to Mar 2018. Clinical characteristics and pathologic backgrounds including H. pylori-antibody positivity, atrophic gastritis and intestinal metaplasia were investigated.

Results: A total of 47 subjects were enrolled consecutively during the study period and analyzed retrospectively. The mean age was 57.19-year-old (range 36 – 85). The male to female ratio was 1.19 (25:21). Endoscopic appearances varied; thirteen subjects presented ulcerative mass (28.26%), 12 (26.00%) flat atypical patch of discoloration, 16 (34.78%) erosive patches, 2 (4.33%) multiple polypoid lesions 3 (6.52%) subepithelial tumor-like appearance. H. pylori infection was proved in 82.6 % (38/46). On histologic examination, background atrophic gastritis-intestinal metaplasia was accompanied by 28.26% (13/46). Serum pepsinogen I and II, as a serological marker for atrophy, was evaluated in 17 subjects. Only 5 of 17 (29.41%) showed compatible with atrophic gastritis (pepsinogen I/H ratio of less than 3).

Conclusion: The background mucosa of gastric MALT lymphoma differs from that of gastric adenocarcinoma in terms of atrophic gastritis-intestinal metaplasia. Less than 30% of gastric MALT lymphoma accompanied background atrophic gastritis, which may be a confounding risk factor. We will prove the unmatched comparison between patients with gastric adenocarcinoma and MALT lymphoma.

Introduction: Anti-TNF-antibody therapy is one of the most potent treatments in Crohn’s disease (CD) for active disease as well as in maintenance therapy, and it might alter the course of disease by preventing irreversible bowel damage and fulminating associated complications. Therefore, since its introduction, anti-TNF-antibodies (TNF-inhibitors) have been used by gastroenterologists progressively earlier in the course of the disease.

Aims and Methods: We aimed to assess the effect of early intervention of TNF-inhibitors in CD patients of the Munich IBD Center on mucosal healing, clinical remission, development of strictures and need for surgery as compared to late intervention within an observation period of 2 years. Early intervention was defined as introduction of TNF-inhibitors within 24 months after first diagnosis of CD and late intervention was defined as intervention after 24 months. In this retrospective cohort analysis we included data from 242 patients from 2007 to 2015 who had received either infliximab (IFX) or adalimumab (ADA) for at least 2 years. Chi2 and T-tests were used for statistical analysis to assess the rates of mucosal healing, clinical remission, stricture disease and need for resective surgery within 2 years after the introduction of TNF-inhibitors. Endoscopic findings of the last ileocolonoscopy before and the first ileocolonoscopy after introduction of TNF-inhibitors provided data on mucosal healing and strictures. Clinical remission was defined as CDAI score of less than 150 points.

Results: A total of 210 treatment with TNF-inhibitors and were assigned to the early intervention group: 45.8% received IFX, 10.7% ADA and 45.5% where switched from IFX to ADA or vice versa. 152 patients met criteria for the late intervention group: 60.0% received IFX, 3.8% ADA and 35.7% were switched from IFX to ADA. Both groups were comparable to sex, genetic susceptibility (NOD2/CARD15), extraintestinal manifestations, presence of bowel strictures and disease activity at the time of introduction. Patients of the early intervention group were younger at start of TNF-inhibitors (26 vs. 32 years; p = 0.001) and more often suffered upper GI- manifestations (23% vs. 3%; p < 0.001). The early intervention group had received less corticosteroids (p = 0.014), 5-ASA (p < 0.001), azathioprine (p < 0.001) and methotrexate (p = 0.057).

Within an observation period of 2 years, patients of the early intervention group never achieved higher mean disease activity rates than patients of the late intervention group (47.5% vs. 25.0%; p = 0.005), they also developed significantly less bowel strictures (10.2% vs. 28.4%; p = 0.008). The combination of absence of mucosal healing and presence of strictures was found significantly more often in the late intervention group (79.5% vs. 53.3%; p = 0.001).

Clinical remission rates 24 months after the introduction of TNF-inhibitors did not differ between the 2 groups. (89.4% vs. 87.9%, p = 0.737).

Within 2 years after introduction, less patients in the early intervention group underwent surgery, however the difference was not significant (17.8% vs. 26.9%, n = 16 vs. n = 41, p = 0.103), possibly due to the small size of the group and the short observation period of only 2 years.

In Crohn’s disease, early introduction of TNF-inhibitors within 2 years after diagnosis is associated with higher rates of mucosal healing and lower rates of complications such as bowel strictures when compared to late intervention. It may also reduce the risk of the need for surgery. We conclude that anti-TNF-antibody therapy could alter the course of disease and prevent irreversible bowel damage.

Introduction: Colorectal cancer (CRC) risk is increased in those with inflammatory bowel disease (IBD). Guidelines advocate surveillance colonoscopy for patients with longstanding IBD. Post-colonoscopy colorectal cancer (PCCRC) is a key quality indicator of colonoscopy. There is limited data exploring the rate of PCCRC in those with IBD and potential risk factors associated with IBD-related PCCRC.

This study explored national and individual hospital rates of IBD-related PCCRC in England since 2006. Further analysis explored potential associations with IBD-related PCCRC in order to inform future quality improvement interventions.

Aims and Methods: We identified all those who had undergone a colonoscopy between 1/1/2006 and 31/12/2012 and developed a CRC before 31/12/2015 using linked national Hospital Episode Statistics and National Cancer Registration data. CRC cases were identified by relevant ICD-10 codes. Using international consensus guidelines, the rate of PCCRC within those with IBD and potential risk factors associated with IBD-related PCCRC.

Introduction: Histological healing may be the ultimate therapeutic goal in ulcerative colitis (UC). Higher vedolizumab trough levels during induction treatment have been associated with better outcomes in UC patients. The association between vedolizumab trough levels and histological healing during maintenance therapy in UC is unknown.

Aims and Methods: In this single-center, retrospective cohort study, we aimed to investigate the association between vedolizumab trough levels and histological healing during maintenance therapy in UC, and to identify potential factors associated with histological healing. Between June 2014 and March 2018, all consecutive patients with moderate-to-severe UC on vedolizumab maintenance therapy who had a histological evaluation and underwent therapeutic drug monitoring within 3 months of this evaluation, were included. Per event analysis was performed. Histological healing was defined as Nancy histological index ≤ 1. Pathologists were blinded to the results of the therapeutic drug monitoring.

Results: 35 histological samples from 31 patients (n = 27 with 1 histological sample; n = 4 with 2 histological samples) were analyzed. Mean (standard deviation) time between histological evaluation and therapeutic drug monitoring was 18.5 (9-26.6) days. Histological healing was found in 18/35 (51.4%) of assessments (n = 15 with Nancy histological index of 0; n = 3 with Nancy histological index of 1). Median (interquartile range) serum vedolizumab trough levels were higher in the group with histological healing compared with the group without histological healing (31.5 (25.4-49.1) µg/mL vs. 15 (9-26.6) µg/mL, p = 0.02). The higher vedolizumab trough levels were associated with higher rates of histological healing (p = 0.004; Table 1). A cut-off vedolizumab trough level of 25 µg/mL predicted histological healing with a sensitivity, specificity, and negative predictive value and negative predictive value of 77%, 71%, 74% and 75%, respectively, leading to an area under the receiver operating curve of 0.62 (95% confidence interval 0.58–0.92; p = 0.006).

Conclusion: This is the first study looking at the association between vedolizumab trough levels and histological healing in UC. Histological healing rates were significantly greater in patients with the highest vedolizumab trough levels during maintenance therapy in UC. A vedolizumab trough level threshold of 25 µg/mL was found most optimal to predict histological healing.

Introduction: Score information on the effectiveness and safety of vedolizumab (VDZ) in inflammatory bowel disease (IBD) is in clinical practice available.

Aims and Methods: We aimed to evaluate the effectiveness and safety of VDZ in IBD. Patients of the ENEIDA registry with active IBD that received VDZ were included. Response was defined based on Harvey-Bradshaw index (HBI) in IBD. Patients of the ENEIDA registry with active IBD that received VDZ were included. 45 [Table 1. Adverse events during vedolizumab treatment.]

Conclusion: Over 60% of IBD patients respond to VDZ treatment, even in a refractory cohort. A relevant proportion of patients discontinue the treatment over time, mainly due to loss of response. CD and disease burden impair both short and long-term response. VDZ seems to be safe in clinical practice.

patients at low risk. We attempted to develop a model to detect patients at risk for early surgery, defined as requiring surgery within 2 years from diagnosis. Aims and Methods: A prospective multicentre inception cohort of newly diagnosed children with CD was established, with progress followed to 2 years post-diagnosis. Phenotypic characteristics, measures of disease severity and inflammation, as well as serological markers were measured at baseline and week 12, and follow-up data were collected at 8, 12, 26, 52, 78, and 104 weeks. Patients undergoing surgery for disease related complications were recorded. Chi-square automatic interaction detection (CHAID) algorithm was used to develop a model with prespecified surgical complications.

Results: A total of 285 patients had data collected with 31(10.9%) needing surgery within 2 years. Multivariate analysis identified strictureing disease at baseline (OR 5.26, 95% CI 2.02–13.67 (p = 0.0001)), and Paediatric Crohn’s Disease Activity Index (PCDAI) > 100 (OR 1.03, 95% CI 1.00–1.07 (p = 0.005)), together with low C-reactive protein (CRP) (OR 0.82, 95% CI 0.70–0.98, (p = 0.025)) at week 12 to be key predictors of the risk for surgery within 2 years. Achieving clinical remission by week 12 modulated the risk for surgery even if strictureing disease was present at diagnosis, while immunomodulators only reduced risk for surgery at follow-up. In our CHAID model, a patient without strictureing disease was present at diagnosis, while immunomodulators only reduced risk for clinical remission by week 12 to be key predictors of the risk for surgery within 2 years. Achieving clinical remission by week 12 to be key predictors of the risk for surgery within 2 years. Achieving clinical remission by week 12 to be key predictors of the risk for surgery within 2 years. Achieving clinical remission by week 12 to be key predictors of the risk for surgery within 2 years. Achieving clinical remission by week 12 to be key predictors of the risk for surgery within 2 years. Achieving clinical remission by week 12 to be key predictors of the risk for surgery within 2 years. Achieving clinical remission by week 12 to be key predictors of the risk for surgery within 2 years.

OP281 MICROSCOPIC POSITIVE TUMOR MARGIN DOES NOT INCREASE THE RATE OF RECURRENCE IN ENDOSCOPIC RESECTED GASTRIC MUSCULAR TUMORS COMPARED TO NEGATIVE TUMOR MARGIN

Y. Zhu, M.-D. Xu, P.-H. Zhou, Q.-L. Li
Endoscopy Center And Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Endoscopy Center, Shanghai, China

Contact E-Mail Address: zhuyn1992521@163.com

Introduction: The endoscopic resection of Gastrointestinal Mesenchymal Tumors (GIMTs) is widely accepted due to its minimal-invasiveness. However, a major concern for endoscopic resection is its high rate of positive microscopic margin which was thought to be related with a higher risk of recurrence. We herein designed this study to examine the effect of R1 endoscopic resection for prognosis of GIMT, featuring a large retrospectively maintained endoscopic resection cohort with long follow up and specimen reevaluation by a single pathologist with expertise on GIMT.

Aims and Methods: This study aimed to find out whether the positive margin affects the recurrence rate of gastric GIMT and the factors associated with positive margin. The patients with gastric GIMTs were recruited in the prospective cohort from January 2006 to December 2017. Indications for endoscopic resection were as follows: (1) GIST or suspected GIST > 2 cm in size or < 2 cm but with rapid growth or high-risk features (e.g. nuclear atypia, high mitotic rate, heterogeneous echogenicity); (2) non-GIST mesenchymal tumors > 2-2.5 cm in size, with rapid growth or high risk features; (3) symptomatic gastric submucosal lesions; (4) undiagnosed gastric submucosal lesions in young patients for whom the risk of resection might be outweighed by the benefit of avoiding lifetime surveillance of these lesions (after careful discussion and informed consent). Clinical and pathological features, endoscopic, and follow-up data were collected and analyzed.

Results: 777 patients were included in the study. All tumors were removed along pseudocapsule without macroscopic residual (ER0) and the median tumor size was 15.2 mm (range 3-100 mm). Pathological evaluation revealed that 37/47(7.7%) gastrointestinal stromal tumors (GISTs). The rate of microscopic R1 resection was 47.0% (443/777). On stepwise multivariate analysis, a significantly increased incidence of R1 resection was recorded in the GISTs (OR 11.13, 95% CI 3.00–41.37). In the univariate analysis of GIST, the univariate analysis revealed that EFTR achieved a higher rate of R0 resection (OR 0.56, 95% CI 0.31–1.00) while it was proved insignificant on stepwise multivariate analysis. Local recurrence occurred in 2 patients during a mean follow-up time of 34.2 months. The recurrence rate of R0 and R1 groups was statistically insignificant (p = 0.841).

Conclusion: Endoscopic resection is a feasible option for the resection of gastric GIMT and has minimal risk of recurrence after a mean follow-up of 34.2 months. The rate of R1 resection is high but is not related to a high rate of recurrence compared to R0 resection. The ER0 resection is sufficient for gastric GIMT.

Disclosure: Nothing to disclose.

Introduction: Over the last decade neoadjuvant chemoradiotherapy (nCRT), preferably the CROSS regimen (carboplatin/paclitaxel + 41.4 Gy radiotherapy), has become standard of care for resectable oesophageal cancer in The Netherlands. About 20% to 50% of patients achieve a pathological complete response (pCR) after nCRT. A pCR is associated with improved survival and the role for surgery is questioned in these patients.

Aims and Methods: The aim of this population-based cohort study was to investigate factors associated with pCR after nCRT and surgery. All oesophageal cancer patients treated with nCRT followed by oesophagectomy in the period 2009-2015 were identified from the Nationwide Netherlands Cancer Registry. Patients with unknown tumour response were excluded. Pathological tumour response was categorized as pCR (ypT0N0) and non-pCR (ypT0N+ or ypT1N0N+ and ypT1N+N+). The 3-year survival rates were compared with log-rank analysis. Univariable and multivariable logistic regression models were used to investigate the association between clinico-pathological variables and pCR. The effect of chemotherapy schedule and radiotherapy dose on pCR were analysed in a subgroup of patients from whom details on neoadjuvant treatment were available. Multivariable Cox regression on overall survival within the group of patients with pCR was performed.

Results: A total of 3533 patients were included and 841 patients (24%) had a pCR (19% in adenocarcinoma and 41% in squamous cell carcinoma). Patients with pCR had higher 3-year survival rate compared to non-pCR patients (68% vs. 48%, p < 0.001). In the non-pCR group, ypT1N+N+ patients had the lowest 3-year survival rate, followed by ypT0N+ and ypT1N0N (respectively, 30%, 52% and 60%, p < 0.001). In multivariable analysis age above 70 years (OR 1.2, 95% CI 1.0–1.5), squamous cell histology (OR 3.0, 95% CI 2.6–3.6), CT1-2 (OR 2.7, 95% CI 1.9–3.7), CT3 (OR 2.4, 95% CI 1.7–3.3), NM (OR 0.74, 95% CI 0.6–0.9) and EN (OR 0.3, 95% CI 0.1–0.7) were associated with higher or lower chance of pCR. In subgroup analysis (N = 668), completion of the CROSS chemotherapy cycles (complete vs. incomplete, p = 0.86) and radiotherapy dose (41.4 Gy vs. > 41.4 Gy) were not associated with pCR. C-reactive protein was inversely associated with overall survival in patients who achieved pCR: were age above 70 years (HR 1.4, 95% CI 1.0–1.7) and less than 10 dissected lymph nodes (HR 1.4, 95% CI 1.0–1.9).

Conclusion: Pathological tumour response is not only determined by treatment-related (e.g. number of dissected lymph nodes) factors, but also by patient-related (e.g. age) and tumour-related (e.g. histology and clinical stage) factors. Completing recommended chemotherapy and/or radiotherapy schedules was not related to pCR in our cohort.

Disclosure: Nothing to disclose.
and urinary volatile organic compounds (VOCs) in patients presenting with lower gastrointestinal symptoms. In this prospective single-centre cohort study 1016 symptomatic patients with suspected CRC referred by general practitioners to secondary care were recruited. A total of 562 patients, who returned stool samples for FIT and FCP and urine samples for urinary VOC measurements and colorectal biopsies, were included in the final statistical analysis. Quantitative FIT was performed on automated HM-JACKiCarc analyser and FCP was measured using the EIA Calprotectin fluorimunoassay on the automated ThermoFisher ImmunoCap 250 analyser. A commercial gas analysis instrument (Lonestar Field Asymmetric Ion Mobility Spectrometry (FAIMS), Owlstone Medical, Cambridge, UK), based on ion mobility spectroscopy (IMS), was utilized to analyse VOCs emanating from urine samples. Various statistical parameters were calculated for each clinical group with 95% confidence intervals (CIs).

Results: The sensitivity and specificity for CRC using FIT were 0.80 (CI: 0.66–0.93) and 0.95 (CI: 0.91–0.95) respectively. The negative predictive value (NPV) was 0.99 (CI: 0.98–1.0). Using urinary VOCs the sensitivity and specificity were 0.63 (CI: 0.46–0.79) and 0.70 (CI: 0.59–0.87) respectively and the NPV was 0.96 (CI: 0.94–0.98). However, for those with FIT negative CRC (false negatives), adding urinary VOCs resulted in sensitivity of 0.97 (CI: 0.90–1.0) and specificity of 0.72 (CI: 0.60–0.76) with NPV of 1.0 (CI: 0.90–1.0).

Conclusion: Faecal biomarkers are useful in excluding CRC patients in symptomatic population with NPV of 99% for FIT. The addition of urinary VOCs showed promise as a second stage test improving FIT performance with NPV of 100% for CRC. It is envisaged that both these non-invasive tests (FIT and urinary VOCs) can be requested within primary care and analysed within a central laboratory at low cost to guide secondary care referral patterns.

Discussion: Educational and financial costs in the reproduction of Thermo Fisher Scientific Ltd. CT has provided educational lectures on behalf of Thermo Fisher Scientific Ltd. All remaining authors disclose no conflicts of interest.

Introduction: Laterally spreading tumors (LSTs) of the colorectum are classified into the following four subtypes according to their morphology; granular homogenous type (LST-GH), granular nodular mixed type (LST-GM), non-granular flat elevated type (LST-NFG), and non-granular pseudo-depressed type (LST-NPGD). Clinical features of each subtype of LSTS have not been fully evaluated.

Aims and Methods: The aims of this study was to clarify the clinicopathological features of colorectal LSTs focusing on their subtypes. We reviewed clinical charts and surgical pathology files of 624 endoscopically resected specimens during January 2007 and December 2017 at our institution. A total of 490 LSTs were detected. We examined the clinical features (mean age, male to female ratio, size, location, Incidence of concomitant carcinoma) according to their subtypes.

Results: Of these 490 lesions, a total of 180 (36.7%) were LST-GH, 43 (8.8%) LST-GM, 233 (47.6%) LST-NFG, and 34 (6.9%) LST-NPGD. Mean age of patients with each subtype was 68.6 years old for LST-GH, 67.0 for LST-GM, 67.2 for LST-NFG, and 66.8 for LST-NPGD. Male to female ratio (M:F) was 1.31 for LST-GH, 1.87 for LST-GM, 1.84 for LST-NFG, and 1.62 for LST-NPGD. Mean size of LST-GH (20.8mm) and LST-GM (25.1mm) were significantly larger than that of LST-NFG (16.7mm) and LST-NPGD (15.3mm). All subtypes were detected predominantly in the proximal colon.

Incidence of concomitant carcinomas in LST-GH, LST-GM, LST-NFG, and LST-NPGD were 17.8% (32 out of 180), 44.2% (19 out of 43), 15.9% (37 out of 233), and 52.9% (18 out of 34), respectively. Incidences of concomitant submucosal carcinoma in LST-GH, LST-GM, LST-NFG, and LST-NPGD were 0% (0 out of 180), 14.0% (6 out of 43), 2.1% (5 out of 233), and 20.6% (7 out of 34), respectively.

Conclusion: Each subtype of LSTS has distinct clinical features. LST-GM and LST-NPGD has provided high-risk polyps than other subtypes. Especially LST-NPGD has the highest risk of invasive carcinoma regardless of its size. Therefore we should carefully detect these lesions and choose appropriate treatment according to the subtypes.

Upper GI sensitivity and symptom generation – Room N1

OP285 GENETIC VARIATION IS ASSOCIATED WITH WORSE AFFECT SCORES, HIGHER SYMPTOM BURDEN, AND MUCOSAL INJURY IN PATIENTS WITH ESOPHAGEAL SYMPTOMS
S. Hasak, A. Patel, B. Nia1, G. Sayuk1, R. Newberry1, C.P. Gaywalla2

Introduction: Genetic variation has been linked to increased symptom burden with esophageal symptoms and functional gastrointestinal (GI) disorders through centrally mediated mechanisms. We evaluated relationships between symptom burden and SNPs in GNB3 (G-protein-coupled receptor in the brain-gut axis), ADRB2 (mediator of stress response), ADAMTS17 (extracellular matrix protein involved cellular junction permeability), SGK3 (treatment response to venlafaxine and susceptibility to anxiety), and FAAH (neuroendocrine regulation, associated with anxiety, IBS, depression), in an enriched population with esophageal symptoms.
Introduction: Minimal inflammation has been reported in functional gastrointestinal disorders (FGID), but the causes of immune activation are largely unknown. Alterations of the stool microbiota have been reported in FGID patients, suggesting specific microbe-host interactions might be a key driver of immune activation. However, these relationships are virtually unexplored in the small intestine. Thus, we aimed to characterise the links between alterations in immune function, the duodenal mucosa-associated microbiome (d-MAM), and gastrointestinal symptoms in FGID patients.

Aims and Methods: 148 patients undergoing endoscopy were recruited in total. GI symptoms were assessed by a standardised questionnaire (SAGIS). Based on all clinical data, the cohort was divided into FGID (n = 88) and non-FGID control patients (n = 60) without relevant structural abnormalities; controls including a positive FOBT and/or iron deficiency anaemia test. Peripheral Blood Mononuclear cells (PBMCs) were isolated from peripheral blood using ficoll density gradient centrifugation. Lamina propria (LP) cells were isolated from duodenal biopsies by collagenase. T-cells in PBMCs and lamina propria were sequenced using Illumina MiSeq technology. Bioinformatics analyses were performed using QIIME and CytoSuite with statistical significance assessed by T-test or Spearman correlation.

Results: There was a significant increase of CD4 gut-homing T-cells in peripheral blood of FGID patients vs controls (p < 0.015). The increase of peripheral CD4 gut-homing T-cells does not lead to an increase of this population in the duodenal LP. Instead, there was positive correlation between effector memory (TEM) cells in duodenal LP, are positively correlated to symptom severity in FGID patients. TEM-cells in duodenal LP, are positively correlated to symptom severity in FGID patients. TEM-cells in duodenal LP, are positively correlated to symptom severity in FGID patients.

Conclusion: Increment in TEM-cells in duodenal LP, are positively correlated to symptom severity in FGID patients. TEM-cells in duodenal LP, are positively correlated to symptom severity in FGID patients. TEM-cells in duodenal LP, are positively correlated to symptom severity in FGID patients. TEM-cells in duodenal LP, are positively correlated to symptom severity in FGID patients. TEM-cells in duodenal LP, are positively correlated to symptom severity in FGID patients. TEM-cells in duodenal LP, are positively correlated to symptom severity in FGID patients. TEM-cells in duodenal LP, are positively correlated to symptom severity in FGID patients. TEM-cells in duodenal LP, are positively correlated to symptom severity in FGID patients. TEM-cells in duodenal LP, are positively correlated to symptom severity in FGID patients.
**OP289** **EXPLORATORY STUDY: COGNITIVE RESTRAINT ASSOCIATED WITH BASELINE VAGAL TONE AND PATHOPHYSIOLOGICAL RESPONSE TO INTERCEPTIVE STIMULUS IN HEALTHY LEAN ADULTS

**Introduction:** The vagus nerve carries sensorimotor information between the brain and gastrointestinal (GI) tract. Vagal tone plays an important role in the regulation of appetite1 and is associated with a range of positive health behaviours. Upon consumption of a meal, internal afferent signals are conveyed to the brainstem depending on the size and nutrient composition of the meal. These are integrated with external sensory information before descending and modulatory pathways elicit an efferent motor response, accompanied by changes in appetite-related sensations. Differences in vagal tone may moderate periprandial responses to interceptive and exteroceptive stimuli and influence eating behaviour. Previously, an interaction between intragastic infusion of fatty-acid (FA) and negative mood induction has been reported to effect behavioural and neural responses in healthy lean subjects.2,3

**Aims and Methods:** The aim of this pilot study was to investigate the relationship between vagal tone and eating behaviour and the effect of the putative interaction between FA and negative mood on appetite-related sensations and food consumption. 10 healthy subjects (3 male, median [range] age 29 [22-32] BMI 22.5 [19.4-24.0]) completed the Three-Factor Eating Questionnaire (TFEQ) and 4 in a 2x2 crossover design. Cardiac vagal tone (CVT), affective state and appetite-related sensations were assessed at baseline and following intragastric infusion of 240 ml 0.05 mol/L C18:1 FA (‘fat’ group) or 0.05 mol/L FA:0-C18:1 (‘fat:sad’ group) at 3 min pre-infusion (-3 min), negative mood induction (‘sad’ condition vs neutral) began, up to 30min post-infusion (PI). Subjects were offered an ad libitum buffet and instructed to eat until comfortably full (40-70min PI). Spearman’s ρ was calculated for baseline CVT against TFEQ scores for cognitive restraint (CR), emotional eating (EE) and unrestrained eating (UE) and the main effect of ‘fat’ or ‘fat:sad’ was tested with ANOVA including ‘condition’ as a within-subject variable for the following (compared to -3min baseline): Δ CVT, Δ fullness (1-100 visual analogue scale), VAS, Δ nausea (1-9 self-assessment nausea, SAM) and Δ negative mood (1-9 SAM) at 20min PI controlling for baseline values; and total energy (kcal) and total fat (g) consumed at 40-70min PI controlling for baseline hunger rating.

**Results:** Baseline CVT (median: 14.12 LVS, range: 2.9–26.8) was negatively correlated with TFEQ-CR (r = -0.74, p = 0.013) but not UE (r = -0.25, p = 0.51) or EE (r = 0.01 p = 0.98). The effect of ‘fat’ on Δ CVT (20min vs -3min PI) was significant (F(1) = 11.13, p = 0.003) and the interaction term approached significance (F(1) = 3.14, p = 0.09). Controlling for baseline ratings, there was no significant effect of either ‘fat’, ‘sad’ or ‘fat:sad’ on Δ fullness, Δ arousal or Δ negative mood. Baseline hunger had a significant effect on the amount of fat consumed (r = -0.74, p = 0.013) and there was no significant effect of condition or interaction on total energy or fat consumption.

**Conclusion:** Relatively high baseline CVT and the strong correlation with CR in this lean sample supports the association between vagal tone and positive cognitive restraint. Small sample size, low dose and volume of fatty-acid infused, and sub-tlety of the mood induction could account for the limited effect of the experimental interventions on subjective ratings and food consumption. However, this exploratory study suggests that CVT could be a non-invasive biomarker of sub-clinical physiological responses. Future work will investigate the role of circulating gut peptides and the relationship between vagal tone and GI motility.

then measured PT for the second time (T00). Only participants with PT drop of ≥ 6 mA (milliampere) measured at (T60) were considered to be sensitised and therefore recruited. After that, participants were randomised in a blinded crossover design to receive either transcutaneous auricular electrical vagal nerve stimulation (tVNS) (pulse width: 250 µs, 25 Hz, cycle: 30 s on, 30 s off), or sham stimulation with the same parameters, for 30 minutes (T60-T90). PTs were measured both, immediately (T00) and 30 min after the end of active/sham stimulation (T120). PTs were analysed using a general linear model for repeated measures with PTs as dependent variables, active/sham as factor and the difference in the initial degree of sensitisation between visits as a covariate (IBM SPSS 23, USA).

**Results:** 18 participants (8 male, mean age 26.6 ± 6.3 years) sensitised and were included. When compared to sham, tVNS significantly increased PT at the end of the stimulation; 19.4 mA (± 21), 2.7 mA (± 12.1), p = 0.01, 95% CI [4.16–27.96]. The effect of tVNS on PT remained significant 30 min after the end of stimulation; 22.5 (± 23.8) vs. 7.69 (± 18.44), p = 0.049, 95% CI [0.079–29.77].

**Conclusion:** Our results suggest that tVNS reverses experimental acid-induced oesophageal pain hypersensitivity in healthy participants. Future studies are warranted to replicate this effect in patients with reflux hypersensitivity and other disorders where pain hypersensitivity is suspected.

**Disclosure:** Nothing to disclose

**Introduction:** In the North American population, colorectal cancer (CRC) incidence for individuals older than 50 years steadily declines, but an opposite trend has been suggested among young adults. In Europe, trends in CRC incidence among younger individuals are lacking.

**Aims and Methods:** The aim of this study was to analyze trends in incidence rates of young adults with CRC in the European Union over the last 25 years.

---

**Disclosure:** Nothing to disclose
Data on age-related incidence of CRC were retrieved from national European cancer registries over a time-frame of at least 10 years, ranging from 1990 until 2016. Young adults, defined as people between 20 to 49 years of age, with confirmed colon or rectal cancer were included. 5-year incidence and mortality rates were calculated, expressed per 100,000 person-years and corrected for age and population trends. Rates were calculated using a Poisson regression analysis, and expressed as annual percent change (APC) with 95% confidence intervals. Results: Data from 20 European countries were included. In adults aged 20 to 39 years of age, the overall CRC incidence rate increased by 4.9% (95% CI: 3.9–5.9) annually since 2005. For colon cancer, incidence rate increased in men by 2.2% (95% CI: 1.4–3.0) per year from 1990-2010 and with an even higher increase of 7.3% (95% CI: 2.3–12.5) per year from 2010-2016. In women the incidence rate increased by 1.5% (95% CI: 0.4–2.7) per year from 1990-2008 and increased even more dramatically by 8.9% (95% CI: 4.8–13.2) per year from 2008-2016. Incidence rate of rectal cancer increased for both men and women, respectively 2.4% (95% CI: 1.9–3.0) and 2.0% (95% CI: 1.2–2.8) per year.

In adults aged 40 to 49 years, the overall CRC incidence rate increased by 1.2% (95% CI: 0.6–1.8) per year from 2002. The incidence rate of colon cancer increased in men by 0.5% (95% CI: 0.1–0.8) per year, and also in women by 0.5% (95% CI: 0.0–1.0) per year. Incidence rate of rectal cancer in men decreased by 3.4% (95% CI: 2.4–4.3) per year from 1990-1997, and then increased from 1997-2016 by 1.6% (95% CI: 0.8–2.3). Rectal cancer in women increased by 8.3% (95% CI: 4.7–12.0) per year in 1990-1996, and remained stable from 1996-2016.

The overall age adjusted mortality rates for CRC did not show a significant trend in adults 20 to 39 years of age. However, mortality rates in adults 40 to 49 years of age decreased by 3.8% (95 % CI: -4.4– -3.2) per year from 1990-2006, and remained stable from 2006-2016.

Conclusions: There is an increased incidence rate in CRC in young adults in Europe. The cause for this trend is still unknown. Awareness and future studies to elucidate causes for this trend are needed and may help to set up screening strategies to prevent and detect these cancers at an early and curable stage.

Disclosure: Nothing to disclose.

OP293 SCREENING FOR COLORECTAL CANCER BASED ON POLYGENIC RISK AND FAMILY HISTORY

D. Cenin, S. Vafeiadou, M. Jenkins, D. Preen, H. Ee, P. O’Leary

Introduction: There is a growing body of evidence that common, low-risk genetic variants play a significant role in colorectal cancer (CRC) risk due to their relatively high prevalence in the population. When combined with family history, they have been shown to improve risk stratification of the general population. We aimed to investigate the impact of risk-based screening (RBS) for CRC, and compare it, in terms of effectiveness and cost-effectiveness, to uniform biennial screening.

Methods: We used the Microsimulation Screening Analysis-Colon (MISCAN-Colon) to model the effects and costs of screening for CRC in a risk stratified Australian population aged 40-74 years. Individuals were placed into one of 5 risk groups based on relative risk (very low, low, average, high, very high) which was determined by their polygenic risk profile and family history of CRC. Screening strategies varied by start age (40, 46, 50, 54 or 50 years), test (no screening, faecal immunochemical test (FIT) and colonoscopy (COL)) and interval (annual, biennial or triennial FIT, and 5- or 10-year COL). Within simulating scenarios of biennial FIT screening for individuals aged 50-74 years and 4 RBS scenarios (R1-4). RBS scenarios increased in complexity: in R1 we modified screening start age, while in R2 we also modified start age and interval and in R3 and R4 we also modified screening intervals. Screening stop age was 74 years for all scenarios. In a sensitivity analysis we included costs for obtaining risk profile which included polygenic testing.

Results: Without screening, 7.8 CRC cases per 1,000 40-year olds were clinically detected over the 50-year follow-up period. This scenario resulted in 26.6 CRC deaths, yielded 23,723 QALYs and cost AUD$2.14 million. Compared to no screening, uniform screening resulted in lower CRC incidence (66.8 cases) and mortality (19.6) and an increased yield in QALYs (23,755 QALYs) and costs (AUD$2.8 million). The RBS strategies resulted in similar CRC incidence and mortality to uniform screening, with the most intensive strategy (R4) having the lowest incidence and mortality. QALYs and costs increased slightly in the RBS scenarios with R4 having the highest yield and costs.

The average cost-effectiveness ratio (ACER) of uniform screening compared to no screening was $1,249 per QALY gained. However, when we considered all strategies, R2, where screening start age and interval were modified, demonstrated cost-effectiveness with an ACER of $1,546 per QALY gained compared to screening start age and interval were modified, and those at highest risk were offered 5-yearly COL, was also cost-effective with an ICER of $10,989 compared to R2. When costs for obtaining risk profile were included, only uniform screening was deemed to be cost-effective.

Conclusion: Our results indicate that RBS determined by common genetic variants and family history is cost-effective, however, overall the gains are small. If, in addition to an earlier start age of screening, individuals at highest risk are offered 5-yearly COL instead of FIT (R4), benefits are expected to be largest. Including costs for obtaining risk profile significantly alters the results, with only uniform screening being cost-effective. The benefits of RBS may alter as new variants are discovered.

Disclosure: Nothing to disclose.

OP294 YIELD OF LYNCH SYNDROME SURVEILLANCE FOR INDIVIDUAL MMM GENES

A. Goverde, A. Wagner, E. Viskil, M. Bruno, R.M.W. Hofstra, M.C.W. Spaander

1Erasmus MC University Medical Center, Gastroenterology & Hepatology, Rotterdam, Netherlands
2Erasmus MC University Medical Center, Clinical Genetics, Rotterdam, Netherlands

Contact E-Mail Address: a.goverde1@erasmusmc.nl

Introduction: Lynch syndrome (LS) is the most common hereditary cause of colorectal cancer (CRC) and is caused by germline mutations in the MMM genes MLH1, MSH2, MSH6 or PMS2. Although different genes may result in different CRC risk, all LS patients are currently offered the same surveillance interval regardless of the gene involved. Therefore, we aimed to assess the yield of LS surveillance for each individual MMM gene carrier group.

Aims and Methods: All patients diagnosed with LS in our center and participating in LS surveillance were included. Patients who had developed CRC before the identification of a MMM mutation were excluded. Data on age, gender, MMM gene involved, number of colonoscopies performed, interval between colonoscopies, and findings at each examination including histopathology were collected. A total of 314 LS carriers were included. Colonoscopy data were available for 264 (84%) patients from 113 different families (38% male, median age at time of first colonoscopy was 44 years (IQR 35-56 years, range 20-80 years). Of these patients, 55 had a MLH1, 44 a MSH2, 143 a MSH6 and 22 a PMS2 mutation. Median follow-up time was 6 years (IQR 2-10 years). At first colonoscopy, adenomas were found in 70 (27%), advanced adenomas in 33 (13%) and CRC in 8 patients (range 46-69 years, 3 MLH1, 1 MSH2 and 4 MSH6 mutation carriers). A total of 916 follow-up colonoscopies were performed in 220 patients. CRC was found in 9 patients, 4 in MLH1 mutation carriers and 5 in MSH2 mutation carriers. No CRC was found in MSH6 or PMS2 mutation carriers. There were no significant differences in the number of colonoscopies with adenomas or advanced adenomas between the different gene mutation carrier groups. In total, 264 adenomas were diagnosed in 101 LS different patients (47% of the patients). Mean number of adenomas per procedure (MAP) was 0.28. Mean number of adenomas per positive procedure (MAP+) was 1.38. There were also no significant differences in time to development of an adenoma or advanced adenoma between the groups adjusted for age and gender. In MLH1 and MSH2 mutation carriers advanced neoplasia (advanced adenoma or colorectal carcinoma) was found in shorter follow-up time than in MSH6 mutation carriers, 6 patients died during LS surveillance. Only 1 patient died from CRC, which was diagnosed at the first colonoscopy. In total 3.6 patients died from pancreatic cancer (1 MSH6 and 2 MSH2 mutation carriers).

Conclusion: Since no CRC was found during follow-up in MSH6 and PMS2 mutation carriers and advanced neoplasia was found in shorter follow-up time in MLH1 and MSH2 mutation carriers, the colonoscopy interval in MSH6 and PMS2 mutation carriers might be less stringent than for MLH1 and MSH2 mutation carriers.

Disclosure: Nothing to disclose.
Results:

122 subjects in each group were required to demonstrate non-inferiority of WLE versus CE for detection of adenomas in patients with LS. We conducted a multicenter randomized study with endoscopists prospectively randomized 1:1 to WLE or CE. The main outcome was the adenoma detection rate (ADR). The ADR for WLE versus CE were as follow: adenomas 1.04 (1.37) versus 0.95 (1.20) (p = 0.015), proximal serrated lesions 10.2% (6.0%-16.6%) versus 7.8% (4.3%-13.7%) (p = 0.183) respectively. The mean (±standard deviation) of lesions per patient for WLE versus CE were as follow: total polyps 50% (41.5%–58.5%) versus 58.7% (58.6%–74.7%) (p = 0.281), sessile serrated lesions 5.5% (2.4%-10.8%) versus 3.9% (1.6%-6.3%) (p = 0.554) and advanced adenomas 7.8% (4.3%-13.7%) versus 3.9% (1.6%-6.3%) (p = 0.183) respectively. The mean (±standard deviation) of lesions per patient for WLE versus CE were as follow: adenomas 1.04 (1.37) versus 0.86 (1.04) (p = 0.069), sessile polyps 2.36 (1.77) versus 2.67 (2.29) (p = 0.004), serrated lesions 0.67 (0.37) versus 0.426 (0.25) (p = 0.01) respectively. The previous colonoscopy was performed with standard definition white-light with adequate bowel preparation. The total procedural time and withdrawal time (mean ± standard deviation; in minutes) were superior in the CE arm: 22.42 ± 4.82 versus 30.67 ± 12.84 (p < 0.001) and 13.5 ± 6.53 versus 18.37 ± 7.57 (p = 0.001) respectively.

Conclusion: In a scenario with expert endoscopists, high-definition WLE is an optimal and efficient endoscopic technique for surveillance of Lynch syndrome patients. CE prolonged the procedural time without increasing detection of relevant lesions.

Introduction: Familial adenomatous polyposis (FAP) is an autosomal dominant disorder that predisposes to colorectal cancer (CRC). It is recommended that patients with FAP are monitored in national databases. The Danish Polypsis Registry is a nationwide, complete registry of FAP patients established in 1977. The aims of this study were to assess the current incidence and prevalence of colorectal cancer in FAP patients, the course of surgical treatment, and finally to compare the course of disease for probands and call-up patients.

Aims and Methods: The annual incidence rate was calculated by dividing number of newly diagnosed cases with the mean population for that year (Statistics Denmark), while the prevalence was calculated by dividing the number of FAP patients with the total population by end of the year (Statistics Denmark).

The complete number of CRC was extracted from Nordcan. Probandes were defined as patients diagnosed due to bowel symptoms and without any knowledge of a secondary malignant disease. Call-up patients were defined as screen detected patients diagnosed at prophylactic examination due to FAP diagnosis in first degree relatives.

Results: By the end of 2017, the Danish Polypsis Registry comprised 221 families with 722 affected individuals, including 610 with histologically verified FAP (309 probands and 311 call-ups). The annual incidence of FAP was 0.13/100,000, while the prevalence by the end of 2017 was 6.04/100,000. During 1999-2017, the proportion of FAP related CRC (n = 34), constituted only 0.05% of the all CRC (n = 72.238) in Denmark. 198 (32%) patients had CRC when diagnosed with FAP. The rate of CRC at the time of the FAP diagnosis was significantly higher in probands compared to call-ups (62% vs 2%, p < 0.0001). Of 610 patients with complete follow-up, 198 (32%) had CRC. Dukes classification was known in 154 patients: 26 (17%) were stage A, 42 (27%) stage B, and 86 (56%) stage C. Colectomy was the preferred surgical modality in 78%, rising from 52% before 1975, to 89% since 2002. The use of colectomy was significantly higher in call-ups (249/249) compared to probands (188/260) (100% vs. 73%, p < 0.0001). Of 295 patients with a known cause of death, 195 (66%) died of CRC, 37 from another malignant disease (13%), while 65 (22%) died from a non-malignant disease.

Conclusion: The Danish Polypsis Registry enables close monitoring of the rate of CRC and quality measurements as the rate of colectomy.

From microbiota to immune mechanisms in CRC carcinogenesis – Room L8

OP297 PROFILES OF BACTERIA-DERIVED EXTRACELLULAR VESICLES IN STOOL, SERUM AND URINE IN PATIENTS WITH COLON CANCER: A PRELIMINARY STUDY

1Seoul National University Bundang Hospital, Internal Medicine, Seongnam, Republic of Korea
2Research & Development Center for BioBankHealing Inc., Seongnam, Korea (Republic of)
3Institute of MD Healthcare Inc., Seoul, Korea (Republic of)

Contact E-Mail Address: gesosyme@naver.com

Introduction: Alternations of gut microbiota is well-known in colorectal carcinoma. Gut microbiota-derived extracellular vesicles (EVs) are widely distributed throughout the body including the blood and urine. In this study, we investigated profiles of bacteria-derived EVs in stool, blood and urine, and evaluated whether they can be a useful marker for the metagenomic analysis of colorectal cancer (CRC).

Aims and Methods: This study incorporated 50 healthy controls and 14 patients with CRC. Information on anthropometric variables, location of tumor, cancer stage, and smoking and drinking habits were collected in patients with CRC. Additionally, we analyzed and compared the bacteria-derived EVs of the stool subjects by using 16S ribosomal RNA gene sequencing of their stool, blood and urine samples, which allowed us to identify over 3,200 operational taxonomic units corresponding to gut microbiota reported in previous studies.
RESULTS: In stool, non-EV bacterial microbiome, microbial diversity was significantly different between CRC patients and controls (Shannon index, p = 0.006); relative abundance of phylum Proteobacteria was decreased (FDR q = 0.003) and abundance of family Bacteroidaceae was increased (q = 0.002).

CONCLUSION: In stool, EV-derived microbiome shows a distinct profile compared to non-EV bacterial microbiome. These results suggest that some of the bacteria-derived EVs such as Comamonadaceae in stool, blood or urine may play a role in colorectal carcinogenesis and might be surrogate markers for the diagnosis of CRC. Further studies are necessary to clarify this issue.

Introduction: Fusobacterium nucleatum (F. nucleatum) is one of the most prevalent bacterial species in colorectal cancer (CRC) tissues and play an important role in colorectal carcinogenesis [1, 2]. A recent study reported Fusobacterium strains were consistently detected in primary tumors and paired metastases, suggesting that Fusobacterium might travels with the primary tumor cells to distant sites, as part of metastatic tissue colonization [3]. However, whether F. nucleatum could drive the metastasis of colorectal cancer is remained to be clarified. We aimed to clarified the role of F. nucleatum in metastasis of colorectal cancer.

Aims and Methods: The abundance of F. nucleatum in fecal samples from CRC patients and healthy people were detected by quantitative real-time PCR. Colorectal cancer cell lines were incubated with F. nucleatum or phosphate buffer saline (PBS control) and analyzed migration and invasion by transwell and wound healing assays. Cells were incubated with F. nucleatum or PBS and injected into tail vein of nude mice and metastasized nodules in the lungs were counted. The relative expression of matrix metalloproteinases (MMPs) were analyzed by quantitative real-time PCR and western blot.

RESULTS: The relative abundance of F. nucleatum was increased in fecal samples of colorectal cancer patients compared with healthy people (N = 30, T = 37). Furthermore, the abundance of F. nucleatum in fecal samples from CRC patients with lymph nodes metastasis was more than patients without metastasis. F. nucleatum co-culture promote CRC cells migration and invasion in vitro. Similarly, injection of CRC cells infected with F. nucleatum. We found MMPs (MMP-1, MMP-3, MMP-9, MMP-12) were significantly upregulated in CRC cells incubated with F. nucleatum versus PBS.

CONCLUSION: Our research firstly provided novel evidence that F. nucleatum promote metastasis of colorectal cancer, suggesting tumor microbiota are essential components of the cancer micro-environment.

Disclosure: Nothing to disclose.

References
(19%) women in the control group. We found a significant increase of IL-2, IL-4, IL-6, IL-17A and IL-23 in the serum of patients with polyposis compared to controls (p = 0.001, p = 0.001, p = 0.01, p = 0.001, 0.001 respectively). We did not detect significant differences of IL-11 and IL-10 between both groups (p = 0.16, p = 0.4). A significant increase of CRP was found in the group of patients with polyposis, where the HOMA index did not present significant differences. We found a significantly higher number of smokers in the group of patients with polyposis than the control group (67% vs 16%, p = 0.001) respectively. Also, a significantly higher percentage of cases had DM (11% vs. 5%, p = 0.06) and 24% of individuals with polyposis developed CC.

Conclusion: The high concentration of CRP and presence of high levels of IL-2, IL-4, IL-6, IL-23 and IL-17A in the group of patients with polyposis indicates the presence of an inflammatory response in these patients. Signaling by IL-23/IL-17A axis along with other cytokines and other factors such as tobacco consumption and DM may be playing an important role in the development of polyposis in these patients.

Introduction: The densities of CD3+ and CD8+ tumor-infiltrating lymphocytes (TILs) and tumor necrosis factor (TNM) are currently key prognostic markers of non-metastatic colorectal cancer (CRC), potentially leading to an innovative Immunoscore forecasting system. FoxP3+TILs, not included in the immunoscore, may as well impact on CRC prognosis. Implementing the immunoscore classification of CRC, we compared the prognostic weight of CD3+ and FoxP3+ TILs, and TNM classifiers for predicting the outcome of patients with stage II and III CRC.

Aims and Methods: The surface covered by FoxP3+ and CD3+ TILs at the invasive front of 413 stage II-III CRC and TNM first classifiers were first challenged by classification and regression tree analysis (CART) by recursive partitioning to identify independent prognostic factors. Significant prognostic factors and their interactions were then re-assessed by logistic regression and Cox modeling, also in a validation set of 215 stage II CRCs.

Results: In the trial set, recursive partitioning recognized an influence of TILs on recurrence risk only within the decisional tree of stage II. Low-FoxP3+ TIL densities (≤0.10 TIL/mm²) were associated with significantly reduced risk of recurrence (HR 0.4) and progression (HR 0.71 for CD3+ TILs). In pooled stage II and III patients with concomitant low TILs the poorest survival, irrespective of allocation to adjuvant therapy (43.5%) or to surveillance (45.5%; p = 1.0).

Conclusion: Combined assessment of independent FoxP3+ and CD3+ TILs accurately forecasted the stage outcome in two independent HL microsatellite-stable CRC patients, eventually outplayed by nodal invasion. By contributing to improved stratification of the recurrence risk, TIL assessment may clarify what patients would benefit from adjuvant chemotherapy in stage II CRC. Conclusions of the measurements of two independent TIL populations can be inspected for determining refined thresholds at which their prognostic (and predictive) value is maximized. The foetalling power of TILs warrants refinement using data from randomized controlled trials, to establish interactions with TNM and the with post-surgical treatments.

Introduction: Insufficient repair of DNA lesions results in the acquisition of somatic mutations and displays the driving force in carcinogenesis. Ribonucleotide incorporation by eukaryotic DNA polymerases occurs during every round of genome duplication and represents by far the most frequent type of naturally occurring DNA lesions. RNAse H2 removes misincorporated ribonucleotides from genomic DNA in a process termed ribonucleotide excision repair (REB). Whether intestinal epithelial proliferation requires REB and whether abrogation of REB is involved in the etiology of carcinogenesis at all is unknown.

Aims and Methods: Mice with an epithelial specific deletion of RNAse H2 subunit b (H2bΔNtC) and co-deletion of the tumor suppressor p53 (H2b/p53ΔNtC) were generated and phenotyped at young and old age. RNA sequencing was performed in isolated epithelial cells and intestinal organs. Mutational signature of spontaneous tumors from H2b/p53ΔNtC mice were characterized using exome sequencing. Association of tumor RNA H2 expression and patient survival was assessed in transcriptome data from 467 CRC patients.

Results: H2bΔNtC mice display chronic epithelial DNA damage and develop a p53-dependent proliferative exhaustion of the intestinal stem cell compartment. H2b/p53ΔNtC mice have restored epithelial proliferation and spontaneously develop small intestinal carcinomas. Resulting tumors display a distinct mutational signature characterized by T > G base substitutions at CpG islands.

Introduction: The cytokine IL-23 is involved in inflammatory bowel disease pathogenesis. A Phase 2, multi-centre, randomised, double-blind, placebo (pbo)-controlled trial (NCT02589665) of mirikizumab (mri; IL-23p19 antibody) was conducted to evaluate mri’s efficacy and safety in patients with moderate-to-severe ulcerative colitis (UC). The primary objective was to evaluate superiority of mri to pbo in inducing clinical remission at wk 12. Other objectives included clinical response, safety, and adjunctive inflammatory markers (faecal calprotectin (FC), serum C-reactive protein (CRP)). The ongoing study’s completed induction phase results are reported here (presented at DDW 2018).

Disclosure: Nothing to disclose

Aims and Methods: The cytokine IL-23 is involved in inflammatory bowel disease pathogenesis. A Phase 2, multi-centre, randomised, double-blind, placebo (pbo)-controlled trial (NCT02589665) of mirikizumab (mri; IL-23p19 antibody) was conducted to evaluate mri’s efficacy and safety in patients with moderate-to-severe ulcerative colitis (UC). The primary objective was to evaluate superiority of mri to pbo in inducing clinical remission at wk 12. Other objectives included clinical response, safety, and adjunctive inflammatory markers (faecal calprotectin (FC), serum C-reactive protein (CRP)). The ongoing study’s completed induction phase results are reported here (presented at DDW 2018).

Disclosure: Nothing to disclose
Aims and Methods: Patients with moderate-to-severe UC (Mayo score of 6 to 12; endoscopic subscore ≥2) were randomized at equal ratios to receive pbo (N = 63), miri 50 mg (N = 63) or 200 mg (N = 62) with possibility of exposure-based increases (2-12-fold or 1.5–3-fold, respectively, up to a 600 mg dose), or a fixed miri 600 mg (N = 61) dose intravenously at wks. 0, 4, and 8. Patients could receive oral 5-ASA or corticosteroids (<20 mg/d prednisone equivalent), thiopurines, must have failed a conventional UC therapy, and could be naive to or had prior exposure to biologics. Endoscopic videos were read centrally by experts blinded to treatment allocation and time point. Comparisons of rates of clinical remission3, primary outcome and clinical response2 were made using logistic regression analysis.

Results: Baseline characteristics were similar among treatment groups, although mean fCLP and CRP levels were higher in the miri 600 mg group. Most patients (63%) had been previously exposed to or failed biologic therapy, with 85% and 11.3% in the pbo and pooled miri (Miri all) groups receiving ≥ 3 biologics, respectively. At wk 12, clinical remission rates were greater (p < 0.01) in patients treated with miri 200 mg, but not miri 50 mg or miri 600 mg, versus pbo-treated patients. Clinical response rates at wk 12 were greater (p < 0.05) for all miri groups, compared to pbo group. At wk 12, fCLP and CRP levels were reduced (p < 0.05 and < 0.01, respectively) in the Miri All group versus pbo. There were similar rates of serious adverse events and treatment-emergent adverse events (TEAEs) across treatment groups.

Conclusion: Miri demonstrated efficacy in the induction treatment for patients with moderate-to-severe UC, as assessed by multiple measures. Miri treatment reduced faecal calprotectin and CRP levels across all doses compared to baseline. Overall adverse event frequencies were similar for miri and pbo-treated patients. These are the first data evaluating the efficacy of an IL-23p19 antibody in patients with moderate-to-severe UC. 20

Introduction: Corticosteroids have been widely used for their anti-inflammatory effects in the treatment of inflammatory bowel disease (IBD). However, corticosteroids have several side effects, such as increased risk of infection, osteoporosis, and Cushing’s syndrome. Therefore, there is a need for alternatives to corticosteroids in the treatment of IBD.

Aims and Methods: In the phase 2 CELEST study of UPA in patients with CD, the new anti-inflammatory agent UPA was shown to be effective in reducing inflammation and improving endoscopic scores in patients with CD. The purpose of this study is to evaluate the efficacy and safety of UPA in the treatment of patients with CD.

Results: In the phase 2 CELEST study, 177 patients with CD were enrolled and treated with UPA. The primary endpoint of the study was the reduction in endoscopic scores at 16 weeks compared to baseline.

Conclusion: The results of this study show that UPA is effective in reducing inflammation and improving endoscopic scores in patients with CD. This study provides evidence for the use of UPA in the treatment of CD and highlights the potential benefits of this new anti-inflammatory agent.

Introduction: Patients with adequately controlled ulcerative colitis (UC) may have a need to stop pharmacological treatment for a range of reasons, including adverse events, to accommodate surgery or transition of care. Tofacitinib is an oral, small molecule Janus kinase inhibitor that is being investigated for UC. This analysis included patients with clinical response to 8 weeks of tofacitinib treatment in OCTAVE Induction 1 & 2 (NCT01465763 & NCT01458951), who were subsequently randomised to receive placebo in the 52-week OCTAVE Sustain maintenance study (NCT014558574), to be a surrogate for treatment interruption.

Aims and Methods: We aimed to evaluate time to treatment failure following treatment interruption for clinical responders to tofacitinib as induction therapy. Treatment failure was defined, based on total Mayo score, as increase ≥3 points from OCTAVE Sustain baseline total Mayo score, plus increase in rectal bleeding subscore and endoscopic subscore ≥1 point and absolute endoscopic subscore ≥2 points. Patients with treatment failure after ≥8 weeks in OCTAVE Sustain were required to discontinue the study. Dropouts due to insufficient clinical response were treated as treatment failures. Event rates for treatment failure and quartile event times were estimated based on the Kaplan-Meier method.

Results: This analysis included 174 patients who had tofacitinib induction therapy and were randomised to placebo in OCTAVE Sustain. Baseline demographics and disease characteristics were consistent with the overall study population (Table): 52 patients (29.9%) were in remission at OCTAVE graphics and disease characteristics were consistent with the overall study. Dr. Van Assche has received consultant fees from AbbVie and other commercial entities. Dr. Reimish has served as speaker and consultant for AbbVie and other commercial entities and received research funding from AbbVie and other commercial entities. Dr. Yacyshyn has research support from MSD. Dr. Sedghi has no conflicts of interest. Drs. Goteti, Lee, and Lacerda are full-time employees of AbbVie and may own AbbVie stock or stock options. AbbVie funded the study, contributed to its design, and was involved in the collection, analysis, and interpretation of the data, and in the writing, review, and approval of the publication. Medical writing support was provided by Maria Hovenden, PhD, Complete Publication Solutions, LLC (North Wales, PA) and was funded by AbbVie.

Introduction: Risankizumab (RZB), an IL-23 inhibitor, as induction and maintenance treatment in patients (pts) with moderate-to-severe Crohn’s disease (CD) have been previously described. Pts whose clinical response or remission to RZB in the Ph2 induction and maintenance study could enrol in an open-label extension (OLE) study. Interim efficacy and safety of RZB maintenance treatment up to 2 years, are reported from the ongoing OLE.

Aims and Methods: Pts who showed clinical response (decrease from baseline [BL] in CD Activity Index [CDAI] ≥100) without remission (CDAI <150) after 2 period (Week 26) or clinical response and/or remission after Period 3 (Week 52) of the preceding study1 were enrolled to receive open-label 180 mg s.c. RZB every 8 weeks for up to 4 years. LTE where pts with missing data or who terminated study participation prior to completion of the preceding study were re-induced with open-label 600 mg i.v. RZB infusions at weeks 0, 4, 8. Pts could only receive subsequent 180 mg s.c. RZB maintenance treatment if they achieved response or remission following re-induction treatment. Hepocellular carcinomas were performed at yearly visits. Treatment-emergent adverse events (AEs) were collected throughout the study participation for up to 15 weeks after the last dose of study drug or up to the data cut-off date of March 31, 2018. Efficacy data (clinical remission and endoscopic remission CDAI 280/200/C20, CDEIS 240/150) for pts with initial isolated ileitis are reported up to week 48, when all pts enrolled in the OLE had the opportunity to reach the visit date before the interim cut-off date. Non-response imputation (NRI) was used for missing data.

Results: A total of 65 pts with CD were enrolled, including 4 pts who were re-induced. At BL of preceding study, median (range) age 34 (19-67) years and median disease duration 10 (2-38) years; 60 pts (92.3%) were previously exposed to TNF-antagonists; 13 pts (23.5%) had previous corticosteroid and immunomodulators treatment, respectively at BL of preceding study. The mean (SD) exposure to RZB was 657.2 (190.73) days (Median: 689; Range: 164-900). As of the data cut-off date, 14 (21.5%) pts prematurely discontinued from the study. At Week 0 of the current study, 48/65 (73.9%) pts were in clinical remission and 28/65 (43.1%) pts had endoscopic remission. Clinical response rates were maintained up to week 48 (Table). The proportion of pts with endoscopic remission increased from BL to week 48 (Table). AEs were reported for 58/65 pts (89.2%) (42.7%) of randomized patients (21.5%) for cytokiniemia (2 pts). No events of tuberculosis, malignancies, or deaths occurred in the study.

Conclusion: SC UST maintained clinical response and remission through 3 years in a substantial proportion of patients, particularly those who were naïve to TNF antagonists. UST was well-tolerated through 3 years, with no new safety signals observed.

**Contact E-Mail Address:** andreas.hadinicolaou@gmail.com

**Introduction:** The aim of endoscopic surveillance of Barrett’s oesophagus (BO) is prevention of invasive adenocarcinoma by detection of early neoplasia. However, in the absence of histologic dysplasia it is difficult to assess the risk of progression. Molecular biomarkers could aid risk stratification. The aim of this study was to assess the utility of a panel of biomarkers on a small number of biopsies in predicting neoplastic progression of BO.

**Aims and Methods:** In a previous prospective study in three European centres we tested 18 and 19 strongly or weakly dysplastic biopsies targeted by autofluorescence imaging for diagnosis of dysplasia. The biomarker panel included p53 and cyclinA immunohistochemistry (IHC), aneuploidy and G2/tetraploidy, hypermethylation of p16, RUNX3 and HPP1, and loss of heterozygosity at 9p and 17p loci. Gorelick et al. found that patients with endoscopic high grade dysplasia (HG) or invasive carcinoma (IMC) were followed up endoscopically. Logistic regression by stepwise selection approach and LASSO regularization was used to select the most predictive biomarkers to form a small panel. Feger’s exact test was used to calculate odds ratios (OR). Means and medians were compared with Mann-Whitney and Student t-test. The primary endpoint was any histologic progression (progression from non-dysplastic BO to any grade of dysplasia or progression from low-grade (LGD) to HGD/IMC). Secondary endpoints included any progression to HGD/IMC and time to progression.

**Results:** Out of 203 patients with BO in the original cohort, 78 were excluded due to HGD/IMC at baseline endoscopy (n=29). LGD treated with RFA at follow-up.

[Table 1. Baseline demographic, endoscopic and histopathological characteristics of patients included in the study]

Logistic regression analysis revealed that p53 and aneuploidy were the only covariates which independently predicted progression to dysplasia (Regression coefficient: 0.91 +/− 0.46 and 1.39 +/− 0.67, respectively). p53 had an OR for any neoplastic progression of 2.94 (CI 1.30–6.66, p < 0.01), while aneuploidy had an OR of 5.37 (CI 1.54–18.76, p < 0.01). Of the remaining biomarkers, cyclinA was a weak predictor but missed statistical significance (p = 0.08). The ORs for progression to HGD/IMC for p53 and aneuploidy were 3.77 (CI 1.53–9.29, p < 0.01) and 6.17 (CI 1.65–23.11, p < 0.01), respectively. When combined into a 2-biomarker panel with a cut-off of 1 positive biomarker, p53 and aneuploidy had OR of 3.66 (CI 1.59–8.45, p < 0.01) for any progression and 4.83 (CI 1.90–12.14, p < 0.001) for progression to HGD/IMC. Moreover, we tested whether the addition of cyclinA improved risk stratification. The 3-biomarker panel with a cut-off of 2 positive markers predicted any neoplastic progression with an OR of 7.57 (CI 1.36–30.81, p < 0.001), and progression to HGD/IMC with an OR of 12.50 (CI 3.43–45.60, p < 0.0001) for progression to HGD/IMC. Finally, among progressors, those with positive biomarker panel had significantly shorter time-to-progression compared to patients with negative biomarker panel (Median 0.42 vs 1.47 yrs, p < 0.01).

Conclusion: In conclusion, we found that a small 3-biomarker panel, comprising of p53, aneuploidy and cyclinA, on biopsies targeted by advanced imaging, is a strong predictor of neoplastic progression in patients with BO and could inform endoscopic management.

Introduction: Prediction for factors determinants of concurrent chemoradiotherapy (CCRT) response has been limited. Patients derived organoid have advantages in providing more physiologically relevant and predictive data for clinical use. We established organoid biobanks with an OR of 12.50 (CI 3.43–45.60, p < 0.01).

Aims and Methods: Patient-derived organoid culture was performed using tumor tissues acquired from esophageal cancer before 1st CCRT start. After 7 days cultured, same sized organoids were collected and were treated with 5-FU and S4 chemotherapy was provided. After 6 days, primary cultured cells were stained and fluorescent images were captured. Clinical response was assessed after 4th cycle CCRT. Clinical response was classified as complete remission (CR), partial remission (PR), and disease progression (PD).

Results: A total of 27 esophageal cancer patients were enrolled. Final success rate of patient-derived organoid culture was 78% (21/27). CCRT response in patient-derived organoids were evaluated in 21 cases. A total of 16 persons were followed up more than 4 cycles of CCRT and were analyzed. Clinical CR was observed in 10 persons and 2 persons showed clinical PR (n = 4) or PD (n = 2). Live activity was noted in less than 10% of organoids in all patients with clinical CR and was observed in 30–40% of organoids in all patients with clinical PD. Live activity was noted in less than 20%–30% of organoids in all patients with clinical PR. Conclusion: It takes 2 weeks to evaluate the CCRT response in organoids from tissue acquirement. High agreement between clinical response and response in organoids was observed. The evaluation of CCRT response in organoids will provide a good predictor of clinical CCRT response and precision medicine.

OP311 THE GUT MICROBIOME INFLUENCES PROGRESSION FROM METAPLASIA TO DYSPLASIA IN THE IL-1β MOUSE MODEL OF BARRETT OESOPHAGUS

1Technical University of Munich, Klinikum rechts der Isar, Klinik und Poliklinik für innere Medizin II, Munich, Germany
2Columbia University Medical Center, Division of Digestive and Liver Diseases, Herbert Irving Comprehensive Cancer Center, New York, United States
3Technical University of Munich, Lehrstuhl für Ernährung und Immunologie, Freising, Germany
4Uniklinik RWTH Aachen, Institut für Medizinische Mikrobiologie, Aachen, Germany
5Massachusetts Institute of Technology, Division of Comparative Medicine, Cambridge, United States

Introduction: The incidence of Oesophageal Adenocarcinoma (OAC) is increasing, with the only known significant risk factor being Barrett’s Oesophagus (BO). Even though there is an association of BO and OAC with obesity and diet, little is known about the responsible mechanisms. Confounding environmental or dietary factors that are prevalent in obese patients might also influence the risk of BO progression. Changes in diet lead to alterations in the gut microbiome and such alterations can have an effect on the susceptibility to gastrointestinal neoplasia. A possible link of microbiome changes in BO and OAC needs to be analyzed in order to understand the role of the microbiome in carcinogenesis or cancer prevention and surveillance strategies.

Aims and Methods: To investigate whether the gut microbiota influences inflammation and tumor development in our mouse model, we used the first time re-derived germ-free (GF) IL-1β mice (IL-1β). We further utilized changes in the diet and housing, specifically a specific-pathogen-free (SPF) and an open cage facility. Using histology and immunohistochemistry the phenotype of the mice was characterized. The microbiota was analyzed using high-throughput DNA sequencing followed by sequence analysis using QIIME and mothur followed by LEfSe. The PICRUSt pipeline was then used for in silico pathway analysis.

Results: IL-1β mice fed with a high-fat diet (HFD) with 48% fat compared to regular lab chow, or HFD matched control diet (Ctrl) showed a more severe phenotype with increased dysplasia. The HFD phenotype could be reproduced in the open cage facility, where we additionally observed an increased phenotype with HFD leading to a further acceleration compared to the SPF. Elimination of the microbiota led to a marked reduction of inflammation, metaplasia and most important dysplasia in the BE mouse model. This correlated with a reduced influx of neutrophils and immature myeloid cells into the esophagus of germ-free IL-1β mice, directly linking the gut microbiome to the inflammatory phenotype. A summary of the increase of the phenotype could be observed with decreasing hygiene level. Since the lower GI tract harbors the majority of the intestinal microbiota, we analyzed the intestinal microbiota by 16S rRNA gene amplicon sequencing of fecal samples. While only a modest reduction in microbial diversity could be observed, analysis of microbial β-diversity showed separate clustering of HFD fed IL-1β mice in comparison to all other groups, due to a unique taxonomic profile. We further observed an altered Firmicutes to Bacteroidetes ratio, correlating with similar alterations of this ratio in patients. Changes in community structure in microbiota from HFD fed IL-1β mice pointed to unique functions. PICRUSt analysis of 16S data generated a predictive metagenome with different clustering of the KEGG data in the IL-1β mice with HFD compared to Chow and IL-1β, suggesting a functional microbial high-fat associated component contributing to disease acceleration. One of the most significantly regulated pathways in the predictive KEGG analysis of the community profile was bacterial polysaccharide biosynthesis,

Conclusion: Our results demonstrate an influence of the gut microbiome on oesophageal carcinogenesis. While the mechanisms responsible for these differences need to be investigated, studies in patients should be performed. Changes in the microbiome of BO patients could be used to identify patients at risk for progression to OAC or the microbiome could be changed by dietary or drug interventions for a more favorable outcome.

**Introduction:** HEROES was a 16-wk double-blind (DB), placebo-controlled, phase 2, multicenter trial followed by a 52-wk open-label extension (OLE) in adults with active eosinophilic esophagitis (EoE) that demonstrated a statistically significant reduction in esophageal eosinophil count and improvements in EoE Endoscopic Reference Score (EERS), EoE Histology Grade, Stage Score (EoEHS), and perception of esophageal severity and symptoms. The objective of OLE was to characterize the effects of RPC4046 for up to 52 wks.

**Aims and Methods:** Patients who completed the 16-wk DB, placebo-controlled period entered OLE and received weekly doses of RPC4046 360 mg subcutaneously and clinical assessments occurred at OLE wks 12, 24, and 52. Outcomes included assessment of mean and peak eosinophil count, EoEHS, EREFS, symptoms (EoE Activity Index [EAI]), and safety. Eosinophilic eosinophil counts and histology scores were determined by a central pathologist. OLE analysis was performed according to the original DB treatment assignment.

**Results:** In the DB period, 99 patients were randomized 1:1:1 to RPC4046 360 mg (n = 33), 180 mg (n = 32), or placebo (n = 34). 90 patients completed the 16-wk DB period, 86 entered OLE, and 66 completed the additional 52 wks of therapy. Mean eosinophilic eosinophil counts (cells/hpf) in OLE remained stable in patients on RPC4046 360 mg or 180 mg prior to OLE but improved rapidly in patients on placebo prior to OLE. Similar effects by treatment group before OLE and received 360 mg in OLE had sustained clinical and histologic improvement of EoE disease activity through 52 wks. Patients who received placebo during the DB period and then received RPC4046 360 mg in OLE showed improvement by wk 12 that was maintained through wk 52. Generally, the overall incidence and types of AEs remained consistent with longer duration of exposure.

**Introduction:** The best approach for Helicobacter pylori management remains unclear. An audit process is essential to ensure that clinical practice is aligned with the latest recommendations and guidelines.

**Aims and Methods:** Our aim was to evaluate the efficacy of most common first-line treatments. International multicenter prospective non-interventional registry starting in 2013 aimed to evaluate the decisions and outcomes of H. pylori management by European gastroenterologists. National coordinators from each country to identify a representative group of recruiters. All infected adult patients were systematically registered at an e-CRF by AEG-REDCap. Variables included Patient demographics, previous eradication attempts, prescribed treatment, adverse events, and outcomes. Intention-to-treat and per-protocol analyses were performed. Data monitoring was performed to ensure the quality of the data.
Results: So far, 21,300 patients from 27 European countries have been evaluated. Average age was 49 years, 60% were women, and 18% had peptic ulcer. The majority of cases (78%, 16,614 patients) were naive to H. pylori treatment. Pre-treatment resistance rates were 24% to clarithromycin, 34% to metronidazole, and 14% to both. Drug prescription and efficacy is shown in the table. Triple therapy with amoxicillin and clarithromycin was the most commonly prescribed (45%), achieving overall < 80% eradication rate. Over 90% eradication was obtained with 10-day bismuth quadruple therapies or 14-day concomitant treatment. Longer treatment duration, higher acid inhibition and compliance were associated with higher eradication rates in the multivariate analysis.

Conclusion: Management of H. pylori infection by European gastroenterologists is heterogeneous, suboptimal and frequently discrepant with current recommendations. Only quadruple therapies lasting at least 10 days are able to achieve over 90% eradication rates.

Introduction: H. pylori eradication is a critical step in the management of gastric ulcer, pylori-related gastritis and other gastric conditions. No medication can be prescribed for or has received research funding from Almirall, Nycomed, AstraZeneca, Casen Recordati, Mayoly and Allergan. Dr. McNicholl has

Aims and Methods: The aim of this study was to explore the potential effects of statin use on the risk of gastric cancer, the results are largely confounded by the presence of other variables (age, sex, comorbidities and the follow-up was censored at GC diagnosis, death or study end date). The observation period commenced from the date of HP therapy initiated in 2 patients with CTLA-4 mutations and in 1 patient with and LRBA (n = 1), TNFAIP (n = 1) and NFKB1 (n = 1). Targeted therapy was initiated in 2 patients with CTLA-4 mutations and in 1 patient with and STAT-3 mutation.

Conclusion: Genetic study of adult patients with non-celiac severe enteropathy with villosity avulsion reveals monogenic disorder in half of cases.

Disclosure: Nothing to disclose

Introduction: Despite successful H. pylori (HP) eradication, some individuals can still progress to gastric cancer (GC). Although statin has been shown to reduce the risk of gastric cancer, the results are largely confounded by the presence of other variables (age, sex, comorbidities and the follow-up was censored at GC diagnosis, death or study end date). The observation period commenced from the date of HP therapy initiated in 2 patients with CTLA-4 mutations and in 1 patient with LRBA (n = 1), TNFAIP (n = 1) and NFKB1 (n = 1). Targeted therapy was initiated in 2 patients with CTLA-4 mutations and in 1 patient with and STAT-3 mutation.

Conclusion: Genetic study of adult patients with non-celiac severe enteropathy with villosity avulsion reveals monogenic disorder in half of cases with possibility of targeted therapy.

5Hospital Carto, Polia (Salerno), Italy
6Hospital Virgen de las Nieves, Digestive Diseases, Granada, Spain
7Royal Cornwall Hospital Truro, Endoscopy, Cornwall, United Kingdom
8Chrischush Hospital, Chirschush, Singapore
9University of Otago Dept. of Medicine, Dunedin, New Zealand
10Ramban Health Care Campus Dept. of Gastroenterology, Gastroenterology,.
Pathology was frequent among the 8 participants (age 46 ± 12 years). In the washout period of sampling 21 ± 5 months, the plastic wrapping was consumed and daily 740 ± 580 mL of water were drank from plastic bottles (11% furry drinks). None was vegetarian and sea fish was consumed by 6 participants (2.6 ± 1.2 kg per month). 5/8 samples have been analyzed so far. The analytical screening identified polystyrene (PS) and polyurethane (PU) plastics in 2 of 5 samples, while in the other samples no definite results are yet obtainable due to high residual cellulose and fat content masking the presence of microplastic.

Conclusion: Increased plastic pollution can cause plastic contamination of foods, which may affect the GI-tract. We are the first to detect presence of polystyrene and polyurethane microparticles in human stool samples. Currently, we are optimizing the stool-sample separation technique of clearing non-plastic particles to further improve quantification and characterization of microplastic load by FT-IR micro-spectroscopy.

Introduction: Fine needle aspiration cytology (FNA) has been the preferred method of specimen evaluation for the past 25 years. Recently, fine needle biopsy (FNB) has become increasingly popular to procure histological core tissue. Although several studies have compared both methods, the impact of FNB on clinical practice is unclear.

Aims and Methods: We aimed to evaluate the impact of FNB on EUS-guided sampling of solid masses over a 4-year period. EUS-FNA using a 22 or 25G needle was the preferred technique for sampling solid mass lesions from 2014-2015 and EUS-FNB using a 22G needle from 2016-2017. Suction was not applied, stylet was not used after the first pass and fanning maneuver was adopted. Per unit policy, after establishing an onsite diagnostic adequacy by rapid evaluation (ROSE), 2 dedicated passes were performed for offsite assessment by cell block preparation. The main outcome measures were 1) Compare the median number of passes required to achieve diagnostic adequacy at ROSE, 2) Compare diagnostic yield at offsite assessment by cell block, which was defined as presence of histological tissue conducive for interpretation.

Results: Of 2020 patients who underwent EUS-guided sampling of solid masses, 2082 (68.9%) underwent FNA and 938 (31.1%) underwent FNB. Lesions were pancreatic 2154 (71.3%), subepithelial 218 (7.2%), lymph nodes 352 (11.7%) or metastatic 152 (4.9%). CCA vs. controls, respectively, MITF (AUC = 0.947) and XRK6 (AUC = 0.936) in controls, LOC441376 (AUC = 0.937) and PHEA1 (AUC = 0.927) in UC vs. controls, CMIP (AUC = 1.000), CCHNB1IP1 (AUC = 1.000) in CCA vs. PSC, and SFRS17A (AUC = 0.991), MTD3 (AUC = 0.980) in CCA vs. controls, respectively.

Conclusion: Aims and Methods: The study’s aim was to evaluate the potential value of serum and urine extracellular vesicles (EVs) as carriers of mRNA biomarkers for various gastrointestinal malignancies. Recent advances in the field of extracellular vesicle research indicate their potential as diagnostic tools.

Introduction: Nucleos(t)ide analogues appear to reduce the risk of hepatocellular carcinoma (HCC) compared to untreated patients due to viro-suppression. However, HCC continues to occur in treated patients with virologic remission. The most important challenge is to identify patients requiring close monitoring of HCC undergoing treatment. For this, many scores were used but appear to have good predictability.

Aims and Methods: The study’s aim was to assess the accuracy of the PAGE-B score and to compare it with other validated scores of other conventional HCC risk prediction models such as REACH B score.

Introduction: Cholangiocarcinoma (CCA) is a very aggressive cancer with a minimal responsiveness to chemotherapies. We have previously demonstrated that CCA is enriched of Cancer Stem Cells (CSCs); these features being associated with aggressiveness and drug resistance. In different solid tumours, DCLK1 has been associated to be a dynamic score that can be calculated during treatment. We have shown that Tunisian patients without cirrhosis with PAGE-B score < 10 had a very low risk of developing HCC within 5 years after treatment and therefore, do not require close monitoring.

Discussion: Nothing to disclose.

Introduction: S100 calcium binding protein A4 (S100A4) which is related to epithelial mesenchymal transition (EMT) is mainly involved in metastasis. Glypican-3 (GPC3) which is mainly expressed during pregnancy in fetal organs regulating morphogenesis has been known to be engaged in HCC development. This study evaluated both S100A4 and GPC3 expression in primary HCC in relation to tumor aggressiveness and diagnosis.

Aims and Methods: Tissues of 70 patients that met the inclusion criteria for hepatocytectomy out of 404 cases of HCC in Egyptian cirrhotic HCV patients were evaluated by immunohistochemistry (IHC) using antibodies against SA100A4 and GPC3 on the slides of tissue microarrays (TMAs) and compared with tumor-adjacent tissue (controls). All patients were followed up for survival, local recurrence and metastasis over a period of at least 6 months.

Results: GPC3 was more expressed in HCC than S100A4 when both were compared to control (79% and 21%), (p < 0.001 and p < 0.0001) respectively while no significant association with GPC3 expression with all three parameters (p > 0.05). GPC3 expression was associated with time of HCC recurrence (p = 0.02) while not with S100A4 (p > 0.05). The mean value of AFP was higher in both positive cases for S100A4 (p = 0.004) and GPC3 (p = 0.04). But in both S100A4 and GPC3 positive cases the overall survival time was affected (p > 0.05). A significant relation was found between overall survival and both S100A4 and GPC3 (p > 0.05). The median overall survival was shorter in decompensated patients and in higher grade tumors (p = 0.012 and p = 0.046 respectively). After univariate regression analysis, the only significant independent predictor for recurrence was decompensation (OR 3.037) and the following independent predictors for metastasis were significant; S100A4 positive staining (OR 9.63) and necrosis (OR 8.33). After multivariate regression analysis, the most significant predictor for metastasis was S100A4 positive staining (OR 8.4). Conclusion: S100A4 could be considered as a prognostic marker for HCC progression as it is related to tumor metastasis, grading and vascular invasion while GPC3 is a reliable marker of HCC diagnosis.

Disclosure: Nothing to disclose.

References
is important to research into safe and practical approaches in management of these patients. In this study we performed an open-label randomized controlled trial with the combined percutaneous injection of ethanol and mitoxantrone (cytotoxic drug with very high affinity to liver cells), has been found to be superior to the injection of ethanol alone in the treatment of Hepatocellular Carcinoma (HCC).

Aims and Methods: Our work is aimed at comparing percutaneous combined local injection of ethanol and mitoxantrone and percutaneous radiofrequency ablation in the treatment of hepatocellular carcinoma. This study excluded patients with more than 1 focal lesion and lesions larger than 4cm. There were 124 patients, 60 were randomized into Group I who were treated with ethanol plus mitoxantrone, while 60 were randomized into Group II who were treated with radiofrequency ablation. Clinical assessment, laboratory evaluation and CT studies were performed to all patients at baseline and at 1, 3, 6, and 12 months post treatment. The primary endpoint was complete ablation of the focal lesion. Data were checked, entered and analysed using SPSS 14 for Windows.

Results: Complete ablation has been achieved in 81.3%, 81.3%, 76.6% and 71.9% of patients in group I at 1, 3, 6 and 12 months respectively, whereas in group II the complete ablation was 88.3%, 88.3%, 85.5% and 81.7% at 1, 3, 6 and 12 months with no statistical significant difference between the two groups. Percentage of complete ablation in small tumours (<2.5cm) is higher than large tumours in both groups. Side effects and complications are significantly higher in group II.

Conclusion: Combined injection of ethanol and mitoxantrone is comparable to radiofrequency ablation with less frequent complications. Ethanol when combined with mitoxantrone can provide a safe, effective and cheaper option for the treatment of HCC especially for small tumours.

OP326 EFFICACY OF PHARMACOLOGICAL THERAPIES FOR THE TREATMENT OF OPIOID-INDUCED CONSTIPATION: SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

Introduction: Opioids are increasingly prescribed in the West, and have deleterious gastrointestinal consequences. Pharmacological therapies to treat opioid-induced constipation (OIC) are available, but their relative efficacy is unclear. We performed a systematic review and network meta-analysis to address this deficit in current knowledge.

Aims and Methods: We searched MEDLINE, EMBASE, EMBASE Classic, and the Cochrane central register of controlled trials through to December 2017 to identify randomised controlled trials (RCTs) of pharmacological therapies in the treatment of OIC. RCTs that reported a dichotomous assessment of overall response to therapy, and were published using a random effects model. Efficacy and safety of pharmacological therapies was reported as a pooled relative risk (RR) with 95% confidence intervals (CIs) to summarise the effect of each comparator, and ranked treatments according to their p-score.

Results: 27 eligible RCTs of pharmacological therapies, containing 9149 patients, were identified. In our primary analysis, using failure to achieve an average of ≥3 bowel movements (BMs) per week with an increase of ≥1 BM per week over baseline, or an average of ≥3 BMs per week, to define non-response the network meta-analysis detected during colonoscopy. The endoscopic classification called “DICA” (Diverticular Inflammation and Complication Assessment) has been recently introduced. Retrospective study found a significant relationship between severity of DICA score and clinical and demographic characteristics of people having diverticulosis/diverticular disease.

Aims and Methods: Aim of this study was to assess the clinical characteristics of patients according to DICA classification and enrolled in a multicentre, international, prospective study.

2215 prospective patients at the first diagnosis of diverticular disease were enrolled after exclusion of radiological signs of acute diverticulitis; inflammatory bowel diseases; ischemic colitis; prior colon resection; patients with severe liver failure (Child-Pugh C) or severe kidney failure; pregnant women; patients who are currently using or who have received any laxative agents or mesalamine or probiotics or antibiotics < 2 weeks prior to the enrollment; inability to comply with study protocol and to give informed consent to the procedure; patients with or history of cancer, of any origin, within 5 years before enrollment; history of alcohol, drug, or chemical abuse. All patients were classified according to DICA classification.

Results: 1377 (62.15%) patients were classified as DICA 1, 599 (27.04%) as DICA 2, and 239 (10.80%) as DICA 3. Table 1 described clinical and demographic characteristics of the enrolled population. We found that the DICA 3 patients, were older, were more frequently females and smokers, had more frequently appendectomy and showed a more than 1 co-morbidity than DICA 1 and DICA 2 patients. Abdominal pain and meteorism were the most frequent symptoms in those people, but DICA 3 patients were more somatic and with more severe expression of symptoms than DICA 1 and DICA 2 people.

Moreover, local calprotectin showed higher levels in DICA 3 than in DICA 1 and DICA 2 patients (p < 0.0001).

No scheduled therapy was generally adopted for DICA 1 patients (53.7%), while it was adopted in only 26.4% and 10.9% of DICA 2 and DICA 3 patients

Introduction: Diverticulosis of the colon is the most frequent anatomical alteration detected during colonoscopy. The endoscopic classification called “DICA” (Diverticular Inflammation and Complication Assessment) has been recently developed in order to have an objective endoscopic description of the colon harbouring diverticula. Retrospective study found a significant relationship between severity of DICA score and clinical and demographic characteristics of people having diverticulosis/diverticular disease.

Aims and Methods: Aim of this study was to assess the clinical characteristics of patients according to DICA classification and enrolled in a multicentre, international, prospective study.

2215 prospective patients at the first diagnosis of diverticular disease were enrolled after exclusion of radiological signs of acute diverticulitis; inflammatory bowel diseases; ischemic colitis; prior colon resection; patients with severe liver failure (Child-Pugh C) or severe kidney failure; pregnant women; patients who are currently using or who have received any laxative agents or mesalamine or probiotics or antibiotics < 2 weeks prior to the enrollment; inability to comply with study protocol and to give informed consent to the procedure; patients with or history of cancer, of any origin, within 5 years before enrollment; history of alcohol, drug, or chemical abuse. All patients were classified according to DICA classification.

Results: 1377 (62.15%) patients were classified as DICA 1, 599 (27.04%) as DICA 2, and 239 (10.80%) as DICA 3. Table 1 described clinical and demographic characteristics of the enrolled population. We found that the DICA 3 patients, were older, were more frequently females and smokers, had more frequently appendectomy and showed a more than 1 co-morbidity than DICA 1 and DICA 2 patients. Abdominal pain and meteorism were the most frequent symptoms in those people, but DICA 3 patients were more somatic and with more severe expression of symptoms than DICA 1 and DICA 2 people.

Moreover, local calprotectin showed higher levels in DICA 3 than in DICA 1 and DICA 2 patients (p < 0.0001).

No scheduled therapy was generally adopted for DICA 1 patients (53.7%), while it was adopted in only 26.4% and 10.9% of DICA 2 and DICA 3 patients
OP328 OUTLET DYSFUNCTION IS PREVALENT IN SEVERE FUNCTIONAL BLOATING: A PROSPECTIVE, MULTICENTER, ITALIAN STUDY

P. Iovino1, M.C. Neri2, L. D’Albà3, G. Chiarioni4
1University of Salerno, School of Medicine and Surgery, Salerno, Salerno (Sa), Italy

4Dipartimento di Scienze della Salute, Università degli Studi di Salerno, Salerno, Italy

Introduction: Bloating and abdominal distension are bothersome symptoms frequently complained about by patients with functional gastrointestinal disorders (FGID). Etiology is unclear in many cases. However, recent studies provided evidence of impaired handling of gas as mechanism potentially relevant to the symptom. Few data are available on defecation behavior in these patients (1). Aims and Methods: Our aim was to study the relationship between the defecation pattern, the severity of bloating and the abdominal girth changes in FGID patients consulting for bloating as prevalent complaint poorly responsive to controlled diet advice. We performed a prospective, multi-center study of patients with severe abdominal bloating (VAS score ≥ 24 on a 100-mm scale) as prevalent complaint with visible abdominal distension. Patients were recruited at 4 gastroenterology outpatient clinics in Italy. Comorbid FGID were grouped according to Rome III criteria. All patients were prescribed a lactose-free diet augmented by NICE dietary advice for irritable bowel syndrome (IBS) for 2 weeks. A belt around the abdomen at standardized sites provided assessment of abdominal girth 2 hours after a meal. All patients reporting inadequate relief of bloating at the end of the run-in underwent a standardized balloon expulsion test (BET) scored as either successful or failed if the balloon could not be evacuated within 2 minutes (2). A straining questionnaire was also administered.

Results: 134 patients (112 female, 39.8 ± 11.9 mean age, 10 IBS-D, 14 IBS-M, 45 IBS-C, 13 IBS-U, 7 Functional Constipation, 36 Functional Bloating, 7 Functional Dyspepsia) completed the 2-week run-in period. Patients completed a daily diary log including abdominal bloating score (100-mm VAS), Bristol Stool Form and stool frequency. At randomization visit, all patients filled in a questionnaire on subjective improvement of bloating on a 5-point Likert scale (true to major improvement) and a further abdominal bloating 100-mm VAS. A belt around the abdomen at standardized sites provided assessment of abdominal girth 2 hours after a meal. All patients reporting inadequate relief of bloating at the end of the run-in underwent a standardized balloon expulsion test (BET) scored as either successful or failed if the balloon could not be evacuated within 2 minutes (2). A straining questionnaire was also administered.

Conclusion: In this prospective, multicenter trial modified NICE diet advice was of clinical benefit in approximately 30% of FGID patients consulting for severe abdominal bloating. Disordered defecation was prevalent in the non-responders and correlated with subjective bloating perception. A biofeedback trial to improve defecation effort is ongoing to investigate the relevance of outlet dysfunction as contributing etiology to functional bloating.

OP330 PREDICTORS OF, AND PREDICTORS OF, A POSITIVE SEHCAT SCAN FOR BILE ACID DIARRHOEA IN GASTROENTEROLOGY OUTPATIENTS: A FOLLOW-UP STUDY

S.J. Lim1, C. Black2, I. Clegg3, F. Chowdhury3, A.C. Ford1

Introduction: Despite recommendations from national guidelines, many clinicians do not perform 23-seleno-25-homo-tauro-cholic acid (SeHCAT) scanning to rule out bile acid diarrhoea (BAD) in patients with chronic diarrhoea [1]. Our previous study auditing the use of SeHCAT scan in our centre showed a yield of 51% in this patient group and identified that patients with terminal ileal (TI) Crohn’s disease or TI resection were highly likely to have an abnormal SeHCAT scan [2]. As a result, we asked clinicians to use a therapeutic trial of a bile acid sequestrant in these patient groups instead of referring them for scanning, hence conserving nuclear medicine resources.

Aims and Methods: In light of changes to the referral criteria, we re-evaluated the yield of SeHCAT scanning in chronic diarrhoea patients, and examined factors predicting an abnormal retention. We retrospectively identified consecutive patients with chronic diarrhoea undergoing SeHCAT scanning at Leeds Teaching Hospitals Trust over a 5-year period from 2012 to 2016. We reviewed electronic patient records to obtain information on presenting gastrointestinal symptoms and any proposed risk factors for BAD. Patients were classified as having irritable bowel syndrome with diarrhoea (IBS-D) if they also reported abdominal pain or discomfort. BAD was categorized into 3 different subtypes (types I, II, and III), and severity (mild: 10–14.9% retention, moderate: 5–9.9%, severe: < 5%). We used a Pearson χ² test to assess the association between a positive SeHCAT scan and any risk factors for BAD.

Results: Between 2012 and 2016, 1071 patients were referred for SeHCAT scanning. As expected, indications for scanning changed between 2012 and 2016, with a significant reduction in referral of patients with TI Crohn’s disease or TI resection year on year (χ² for trend, p < 0.001). Despite this, 457 (42.7%) patients had BAD and there was no downward trend in yield of SeHCAT scanning during the 5-year study period (χ² for trend from 2012–2016, p = 0.39). This remained the case when data were compared with the previous 7-year study.
period from 2005 to 2011 (χ² for trend from 2005-2016, p = 0.28). The proportion of patients with type II and III BAD increased from 2012 to 2016 (χ² for trend, p < 0.001). Overall, 51.6% had type II BAD, 36.1% type III, and 12.3% type I. BAD was mild in 31.7%, moderate in 34.4%, and severe in 33.9%. Of the 453 patients with IBS-D symptoms, 154 (33.7%) had a positive SeHCAT (Table 1), indicating type II (idiopathic) BAD. In total, 653 (61.0%) patients had no known risk factor for BAD, other than chronic diarrhoea, but 233 (35.7%) of these individuals had BAD, with 143 (61.4%) of them having moderate or severe BAD.

3. Jørgensen P, Bouchelouche D, Rainteau S, Layani-Moreno L, Munck L. The prevalence of Bile Acid Diarrhoea (BAD) is 1% in the general population and up to 32% in patients with diarrhoea-predominant irritable bowel syndrome (1). Availability of the diagnostic scintigraphic SeHCAT retention test is limited. 7α-hydroxy-4-cholesten-3-one (C4) is a proposed diagnostic alternative to SeHCAT (2, 3). Compared with SeHCAT, fasting Fibroblast Growth Factor-19 (FGF19) has an average diagnostic strength (4) but our pilot study suggested that the FGF19 response to a meal plus chenodeoxycholic acid (CDCA) stimulation may have diagnostic strength comparable with that of C4 (5).

### Aims and Methods:

We aimed to validate the biochemical tests C4 and the response in FGF19 to a meal plus CDCA with the SeHCAT test (NCT03059537). We prospectively recruited patients referred for SeHCAT at four Danish centres to compare SeHCAT, C4, and stimulated FGF19. Exclusion criteria included cirrhosis, ileal resection, active IBD, and use of laxatives or anti-diarrhoeal drugs 1 week before SeHCAT visit 1 and during the study. At SeHCAT visit 1 patients started a 6-day Bristol Stool Form (BSF) diary. At SeHCAT visit 2 we sampled fasting blood, subjects ingested 1250 mg CDCA and a solid meal (2 boiled eggs, 2 slices of toast bread, and 500 mL water). Plasma was sampled after 90, 120, and 150 minutes. We analysed FGF19 by enzyme-linked immunosorbent assay and C4 by high-performance liquid chromatography-tandem mass spectrometry. SeHCAT ≤ 10% defined BAD and SeHCAT > 10% defined idiopathic diarrhoea. Data are presented as median and interquartile ranges. Continuous variables are compared with the Mann-Whitney U-test.

### Results:

Of 71 subjects, 26 (9 male) had BAD and 45 (27 male) had idiopathic diarrhoea. Median age was 45 years (34-49) vs. 55 years (45-64); p < 0.01. Average stools per day was 3.9 (3.0-5.3) vs. 3.0 (2.0-4.0); p = 0.01. Average BSV was 5.9 (5.5-6.3) vs. 5.6 (5.0-6.2); p = 0.17. After the CDCA ingestion, the plasma C4 values peaked at 90 minutes and FGF19 peaked at 150 minutes, with no significant difference in values between patients with BAD or idiopathic diarrhoea except for FGF19 at fasting; p < 0.01. Table 1 shows biochemical results and the receiver operating characteristics (ROC) analysis with predefined and proposed cut-off values. With C4 < 15.4 ng/mL as the cut-off for a definite negative test, 40 of 71 subjects were C4-negative; 34 of these 40 (85%) were true negative. With C4 > 45.1 ng/mL as the cut-off for a definite positive test 12 of 71 subjects were C4-positive, and 10 of these 12 (83%) were true positive. This diagnostic algorithm left 19 of 71 subjects with an inconclusive C4-test, of which 10 had SeHCAT ≤ 10%. A similar algorithm for fasting FGF19 with the cut-off values shown in Table 1 left 33 subjects with an inconclusive FGF19 test.

### Conclusion:

Stimulation with a meal plus CDCA does not increase the diagnostic yield of FGF19 for diagnosing BAD. In our population, C4 is the superior biochemical test and qualifies for a screening test. This needs further validation with the treatment response in a controlled trial.

### Disclosure:

Sigma-tau Rare Disease Ltd. provided CDCA (Xenbilox) without restrictions as an independent grant.

OP332 EXPOSURE TO MICROBIOTA EARLY IN LIFE DETERMINES COLITIS SEVERITY IN ADULT MICE

Z. Al Nabhani, S. Dulauroy, G. Polomack, R. Eberl
Institut Pasteur, Paris, France

Contact E-Mail Address: ziad.alnabhani@pasteur.fr

Introduction: The etiology of inflammatory bowel diseases (IBD) remains complex. Increasing evidence supports the view that perturbation of the immune system may interact with the intestinal microbiota via an increased susceptibility to IBD in adulthood. However, how perturbations in host-microbial symbiosis and immunity in childhood impact the intestinal immunity later during adulthood remains enigmatic.

Aims and Methods: In this study, we explored the early time window, and the underlying mechanisms, during which microbiota impacts the IBD susceptibility later in life. Germ-free mice were colonized with microbiota before or after weaning and their susceptibility to develop colitis induced experimentally by dextran sulfate sodium was assessed at adult age. Immune responses, microbial metabolites and microbiota composition were determined during weaning and/or before colitis induction at adult age.

Results: We identified weaning as a window of opportunity during which exposure to microbiota determines the severity of experimental colitis in adult mice. We showed that exposure to microbiota during weaning, but not later, induces an immune response that contributes to regulate the severity of colitis in adult mice. RNA-seq analysis in the colon before colitis induction of GF mice exposed to microbiota before or after weaning revealed immune abnormalities associated with different type of cells. The underlying mechanisms involve microbial metabolites, such as short chain fatty acids (SCFAs), the administration of which downregulates pre-weaning colitis severity in adult age. This protective effect of SCFAs early in life is dependent on the cross-talk between intestinal epithelial cells and regulatory T cells expressing the transcription factor RORγt (Retinoic-Acid Receptor-related Orphan Receptor gamma t).

Conclusion: These results validate how host-microbial symbiosis during a specific time window of opportunity early in life determines long-term susceptibility to inflammatory pathology.

OP333 ULCERATIVE COLITIS PATIENTS IN LONG-TERM STABLE REMISSION RECOVER EUBIOTIC CHARACTERISTICS OF THEIR MICROBIOTA

C. Herrera-deGuise, E. Varela, V. Robles, F. Casellas, N. Borruel Sainz, F. Guarrner
Unitat Atenció Crohn-Colitis (UACC), Hospital Universitari Vall d’Hebron, Barcelona, Spain

Contact E-Mail Address: cherreradeguise@gmail.com

Introduction: Ulcerative colitis (UC) and Crohn’s disease (CD) are inflammatory bowel diseases characterized by an aggressive immune response thought to be propagated by microbial metabolites. There are limited data concerning microbiota in UC patients with long-term remission. We determined whether patients with UC in long-term remission have microbiota that is similar to healthy controls. UC patients

Aims and Methods: To evaluate the microbiota in UC patients in long-term remission. A cross-sectional study was performed in 4 groups of subjects: 1) UC-L: UC patients in long-term remission (≥5 years of flare-free disease, with clinical, endoscopic and histological remission at time of study); 2) UC-S: UC patients in short-term remission and high relapse rate (3 months in clinical remission at time of study and previously more than 1 relapse per year); 3) UC-F: UC patients with active disease (SCCAI > 4 at time of study) and 4) HC: healthy unrelated controls. We obtained 2 frozen stool samples from all subjects, except from the UC-F group from which we obtained 1 frozen stool sample at the beginning of the flare. Total bacteria, F. prausnitzii, A. muciniphila, E. coli and F. nucleatum were measured by quantitative Real Time PCR (qPCR, copies/g stool).

Results: 112 subjects were included, 29 in UC-L group, 20 in UC-S, 39 in UC-F and 24 HC. Median age of UC patients was 39 years and in HC was 34 years, women comprised 52% of all UC and 58% of HC. F. prausnitzii abundance was significantly higher in UC-L and UC-F compared to the UC-L group (median 7.67E+8 copies/g; 5.06E+8 copies/g vs. 4.37E+9 copies/g, p < 0.05). A. muciniphila abundance was depleted in both UC-S and UC-F in contrast with UC-L and HC (median 0.00E+10 copies/g in UC-S and UC-F vs. 3.98E+6 copies/g in UC-L and 5.01E+9 copies/g in HC, p < 0.01). E. coli and F. nucleatum abundance was similar in all subjects studied.

Conclusion: UC patients in long-term, stable remission present an abundance of A. muciniphila and F. prausnitzii that is similar to healthy controls. UC patients may be able to recover some eubiotic characteristics of their microbiota and this could become an important therapeutic end-point in UC.

Disclosure: Nothing to disclose

OP334 COMPARISON OF INTESTINAL MICROBIOTA COMPOSITION IN PATIENTS WITH ULCERATIVE COLITIS DEPENDING ON THE PLACE OF RESIDENCE (URBAN OR RURAL)

N. Danilova1, M. Markelova1, S. Abdulkhakov2, T. Grigoryeva1, A. Odintsova2, R. Abdulkhakov2
1Kazan Federal University, Kazan, Russian Federation
2Republican Clinical Hospital of Tatarstan Republic, Kazan, Russian Federation

Contact E-Mail Address: sayarbuld@yandex.ru

Introduction: The gut microbiota composition differs at the inter-individual level and depends on many factors as food, geographical conditions of human living, genetic factors, age, etc. It is probably the change in the composition of the gut microbiota which can lead to the activation of immune inflammation in ulcerative colitis and Crohn’s disease patients.

Aims and Methods: The aim of the study was to reveal the influence of the place of residence (urban/rural) on the composition of intestinal microbiota in inflammatory bowel diseases (IBD) patients.

Materials and methods: The study included 91 patients with ulcerative colitis and Crohn’s disease (22 living in urban, and 69 – in the urban area). The control group consisted of 96 healthy subjects (25 from rural and 69 from urban area). Total DNA was extracted from stool samples followed by whole genome sequencing (SOLiD 5500 W platform).

Results: The following bacteria were predominant in the samples of healthy subjects living in a rural area: Clostridium (3.20±5.64)%; Eubacterium (16.86±8.19)%; Butyribrio (1.46±0.67)%; Coprococcus (8.82±0.82)%; Roseburia (5.79±4.02)%; Faecalibacterium (7.89±4.93)%; Ruminococcus (12.63±11.51)% and Akkermansia (1.46±0.40)% in contrast to the group of patients, living in a rural area: Clostridium (0.11±1.80)%; Eubacterium (8.34±0.87)%; Butyribrio (0.79±2.59)%; Coprococcus (4.81±1.73)%; Roseburia (3.11±1.53)%; Faecalibacterium (3.64±3.61)%; Ruminococcus (3.92±0.03)%; Akkermansia (0.08±0.21)%; p < 0.05. In the group of healthy urban residents bacteria: Clostridium (0.99±3.58)%; Eubacterium (13.68±9.59)%; Butyribrio (1.77±5.83)%; Coprococcus (5.95±6.46)%; Roseburia (3.48±3.75)%; Faecalibacterium (5.73±5.58)%; Ruminococcus (7.31±6.70)%; Akkermansia (2.29±7.26)% were much more abundant than in IBD patients living in the cities. However the abundance of Bacteroides genus was significantly higher in groups of both rural and urban IBD patients: (14.45±18.02)% and (21.8±19.11)% compared to the control group of healthy subjects living in rural and urban areas (2.73±1.75)%; (9.05±12.08)%, respectively, p < 0.05. The abundance of Bacteroides vulgatus was elevated in IBD patients both from rural (3.84±4.02)% and urban areas (7.28±9.57)% compared to the control group of subjects form rural (0.43±0.52)% and urban areas (2.09±3.46)%; p < 0.05. Comparative analysis of microbiota of IBD patients living in rural and urban areas revealed differences in the representation of only 2 genera of bacteria: the abundance of Methanosphaeribacter (2.30±6.19)% and Catenibacterium (1.18±1.93)% was higher in patients living in the cities (0.71±2.72)% and (0.38±0.85)%, respectively, p < 0.05.

Conclusion: Only 2 genera of bacteria – Methanosphaeribacter and Catenibacterium – differed significantly between urban and rural IBD patients. The abundance of butyrate-producing bacteria with anti-inflammatory properties (Butyribrio, Eubacterium, Faecalibacterium, Coprococcus, Ruminococcus, etc.) was significantly decreased in IBD patients comparing to healthy subjects. The abundance of B. fragilis, which is the cause of diarrhea of different etiology, was statistically different between the groups, but there was an increase in its relative representation in the group of urban IBD patients.

Disclosure: Nothing to disclose

OP335 DONOR MICROBIOTA AS A DETERMINANT FACTOR FOR RESPONSE TO FMT IN PATIENTS WITH ULCERATIVE COLITIS

Introduction: Fecal microbiota transplantation (FMT) is an experimental approach for the treatment success of FMT in UC patients. This is an open labeled trial of repeated FMT for steroid resistant or dependent ulcerative colitis patients (n = 50). Demographic and laboratory findings of donor and recipient were...
recorded. Fecal samples of donors and patients were analysed by 16S rRNA gene-based microbiota analysis in only 10 patients (related donors).

**Results:** 16/50 (32%) of patients showed complete response and 4/50 (8%) had a partial response to FMT. Response was mainly influenced by the taxonomic composition of the donor’s microbiota. Stool of donors with a high bacterial richness (observed species richness 811 ± 74 vs no response 644 ± 168 at 15996 rps) and a high relative abundance of Akkermansia muciniphila (4.2 ± 2.1% vs 0.3 ± 0.1%), Faecalibacterium prausnitzii (11.9 ± 3.0% vs 6.2 ± 2.9%), and Ruminococcus spp. (15.2 ± 3.2% vs 1.1 ± 0.8%) were more likely to induce response. Demographic data were also analysed. Multivariate analysis showed the duration of illness longer than 1 year was a negative predictive factor (0.72 (0.57–0.92) p < 0.01).

**Conclusion:** The taxonomic composition of the donor’s intestinal microbiota is a major factor influencing response for FMT. Further artificial microbial preparations for ideal microbial match should be investigated. Duration of illness is a significant factor for success of FMT and early application of FMT in UC should be studied in further well-designed trials.

**Introduction:** Mucosal ATP depletion as the consequence of reduced mitochondrial respiratory chain activity has been attributed to ulcerative colitis (UC) pathogenesis more than 30 years ago. Mucus producing goblet cells, which are highly dependent on energy supply via the oxidative phosphorylation (OXPHOS) system, are supposedly highly affected by reduced OXPHOS activity. Furthermore, reduced numbers of goblet cells and intestinal mucus depletion have been suggested as histological hallmarks of UC. Finally, mucus composition and glycosylation is able to shape the intestinal microbiota, which is frequently altered in UC patients. Nevertheless, experimental evidence linking mitochondrial dysfunction with intestinal mucus depletion and microbiome alterations are still missing.

**Aims and Methods:** Mucus producing HT29MTX cells as well as marine intestinal organoids are employed as in vitro or ex vivo model systems, respectively, in order to study mucin transcription, production, secretion and glycosylation upon energy metabolism modifying stimuli. In vivo, conplastic mice, carrying well-characterized single nucleotide polymorphisms in their mitochondrial genome, are studied on their susceptibility to various experimental colitis models. Furthermore, seahorse analyzer is used to control for mitochondrial respiration and glycolysis, while microbiome composition is analysed via 16srRNA next generation sequencing.

**Results:** In vitro stimulation of HT29MTX cells showed that mucus transcription and secretion is highly dependent on mitochondrial OXPHOS capacity. In line with this, mice with reduced mucosal ATP levels and OXPHOS activity depicted goblet cell reduction and increased susceptibility to DSS colitis, characterized by elevated DAI, MEICS and histologic scores. On the other hand, mice with increased mucosal ATP levels were protected against experimental colitis. Finally, gut microbial composition was highly dependent on mitochondrial genetics.

**Conclusion:** Taken together, we here describe a new pathway linking major hallmarks of UC. Mitochondrial OXPHOS activity and mucosal ATP levels in intestinal epithelial cells might be strongly underestimated factors in UC pathogenesis and therapeutic potentialities.

**Introduction:** Changes in gut bacterial community structure are associated with Crohn’s Disease (CD) development and response to therapy including reduced diversity, temporal instability, and shifts in abundances of many bacterial species. Bile acid (BAs) play a central role in modulating the immune response, and changes in the BA pool are also associated with gut bacterial activity. The liver synthesizes and conjugates the primary BAs while bacteria deconjugate, epimerize and dehydroxylate in the production of the secondary BAs. The predominant primary BAs are cholic acid (CA) and chenodeoxycholic acid (CDCA), and the predominant secondary BAs are lithocholic acid (LCA) and deoxycholic acid (DCA). Because the gut microbial community impacts the BA pool, it is possible that community changes could affect the BA-receptor mediated immune response.

**Aims and Methods:** The relationship between the gut microbiome and the BA pool, both obtained from stool samples collected at baseline, during exclusive enteral nutrition therapy (up to week 12) and then at 12-week intervals to 48 weeks follow-up, was investigated in 16 pediatric CD patients. Patient outcomes were classified as: sustained remission for >24 weeks (SR), non-sustained remission (NSR) or non-remission (NR). Taxonomic marker (16S) and metagenomic sequencing was performed on the stool samples. Taxonomic and functional assignments were made using QIIME and HUMAN2, with diversity statistics computed using QIIME. Bile acid profiles were obtained from stool by liquid chromatography tandem mass spectrometry. Standard statistical tests were performed using R, and the relationship between microbial community structure and BA composition was inferred using a hierarchical Bayesian model (BioMiCo).

**Results:** 2 groups of patients were identified that differed in both BA profile and gut microbiome. The first group was associated with high amounts of the secondary bile acids LCA and DCA, and was comprised of SR. NSR and NR patients. These patients had relatively high levels of microbial alpha diversity, with Ruminococcus obeum, B. torques, Bacteroides uniformis, B. vulgatus, several species of Alistipes and Subdoligranulum being predominant lineages. The second group was associated with high amounts of unconjugated primary bile acids and 2 other secondary bile acids, ursodeoxycholic acid (UDCA) and hyodeoxycholic acid (HDCA). This group was comprised exclusively of NSR patients. Alpha diversity was lower in these patients, with R. gravis, B. plebeius, B. eggerthii, Clostridium boccace, and C. innocuum being predominant lineages. A survey of bacterial BA genes within the metagenome revealed that most samples contained the bile salt hydrolase gene responsible for deconjugation. The bacterial genes responsible for conversion to secondary bile acids were much more restricted.

**Conclusion:** Primary BAs levels differed significantly between the SR and NSR patients. Moreover, high primary BAs were seen only in NSR patients. The presence of HDCA in the second group of patients (all NSR) is noteworthy, as HDCA has a detergent like effect leading to membrane disruption, and is suggested to induce strong cytotoxicity, apoptosis, and IL-8 synthesis. Based on these findings, we speculate that there may be a microbial community that leads to increased HDCA and impacts the ability to sustain remission.

**Disclosure:** Nothing to disclose.
In our NASH clinic, about a quarter of the referred patients were reported following liver biopsy.

**P0001** MEDICAL EVALUATION ON SUSPICION OF NON-ALCOHOLIC STEATOHEPATITIS (NASH): REAL-WORLD OUTCOME FROM A COMMUNITY NASH CLINIC

**Aims and Methods:** During 2017, patients from Bispebjerg Hospital clinics with a suspicion of NASH were referred to the NASH clinic. Suspicions of NASH were based on having at least 2 of the following risk factors: BMI ≥25 kg/m², or persistent ALT > 80 U/l. Based on a general work-up algorithm and an individualized approach, routine and NAFLD specific examinations were performed to exclude other causes of chronic liver disease (CLD). To diagnose and assess NAFLD grade and fibrosis stage, structured interview including thorough medical history, anthropometric measurements, NAFLD (hepatic, metabolic and fibrosis) blood tests (no genetics), ultrason. US-echography and US-guided liver biopsy was offered as appropriate. NASH diagnosis and fibrosis stage was based on histopathology. NAFLD activity, NAFLD fibrosis and FIB-4 index scores were calculated. Numbers of patients, percentages of total (%), medians (upper range-lower range) and means ± standard deviation were reported, as appropriate.

**Results:** 55 adult patients were referred to the NASH clinic on suspicion of NASH: 12 patients (22%) were found to have non-NAFLD CLD (including hepatocellular carcinoma) and 43 patients (78%) were classified as NASH. Of these, 26 people, F1, and if CUM10 > 5.0, then a = 1, if CUM20 < 2.50%, then b = 1, if and if CUM30 < 5.65%, then c = 1, if CUM30 > 5.65%, then c = 0, to determine the degree of fibrosis of the liver as F0, which is corresponding to the presence of portal fibrosis, at a value of N = 1–3, the liver fibrosis of F2-3, corresponding to the presence of portal fibrosis without septa and with a small number of septa, with a value of N = 10–13, determines the degree of fibrosis of the liver F3-4, which is determined by the degree of liver cirrhosis and cirrhosis. The invention is based on the first time we established a constant relationship between the cumulative dose of 13C-MBT and the presence of liver fibrosis.

**Conclusion:** The results of the method of assessing fibrosis with the 13C-MBT in the determination of the degree of liver fibrosis, corresponded to the values of the liver biopsy, fibrotests, elastometry. N = 1a + 2b + 10c, where is the number of scores, a is the coefficient calculated from the cumulative dose of 13C for 10 min-1 in% (CUM10), b - the coefficient calculated from the cumulative dose of 13C for 20 minutes in% (CUM20), c is the coefficient calculated from the cumulative dose of 13C for 30 minutes in (CUM30), if CUM10 < 1%, then a = 1, if CUM10 > 1.00%, then a = 0, if CUM20 < 2.50%, then b = 1, and if CUM20 > 2.50%, then b = 0, if CUM30 < 5.65%, then c = 1, if CUM30 > 5.65%, then c = 0, and for N = 0, determine the degree of fibrosis of the liver as F0, which is corresponding to the presence of portal fibrosis, at a value of N = 1–3, the liver fibrosis of F2-3, corresponding to the presence of portal fibrosis without septa and with a small number of septa, with a value of N = 10–13, determines the degree of fibrosis of the liver F3-4, corresponding to the presence of numerous septa without cirrhosis and cirrhosis. The invention is based on the first time we established a constant relationship between the cumulative dose reduction indices 13C at the 10th, 20th and 30th minute 13C-metacetinologo performing the breath test and the risk of the presence of liver fibrosis in patients with CLD.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** ebrahimg27@gmail.com

Introduction: Steatohepatitis (NASH) with fibrosis is the phenotype of non-alcoholic fatty liver disease (NAFLD) that carries the highest risk of developing end-stage liver disease and the associated serious complications including cardiovascular disease. In line with recent international and national Danish guidelines for the management of NAFLD patients, we established a community NASH clinic including a multi-disciplinary-team. We here report our initial experience and real-world outcome for medical evaluation of referred patients on suspicion of NASH.

**Conclusion:** The results of the method of assessing fibrosis with the 13C-MBT in the determination of the degree of liver fibrosis, corresponded to the values of the liver biopsy, fibrotests, elastometry. N = 1a + 2b + 10c, where is the number of scores, a is the coefficient calculated from the cumulative dose of 13C for 10 min-1 in% (CUM10), b - the coefficient calculated from the cumulative dose of 13C for 20 minutes in% (CUM20), c is the coefficient calculated from the cumulative dose of 13C for 30 minutes in (CUM30), if CUM10 < 1%, then a = 1, if CUM10 > 1.00%, then a = 0, if CUM20 < 2.50%, then b = 1, and if CUM20 > 2.50%, then b = 0, if CUM30 < 5.65%, then c = 1, if CUM30 > 5.65%, then c = 0, and for N = 0, determine the degree of fibrosis of the liver as F0, which is corresponding to the presence of portal fibrosis, at a value of N = 1–3, the liver fibrosis of F2-3, corresponding to the presence of portal fibrosis without septa and with a small number of septa, with a value of N = 10–13, determines the degree of fibrosis of the liver F3-4, corresponding to the presence of numerous septa without cirrhosis and cirrhosis. The invention is based on the first time we established a constant relationship between the cumulative dose reduction indices 13C at the 10th, 20th and 30th minute 13C-metacetinologo performing the breath test and the risk of the presence of liver fibrosis in patients with CLD.

**P0003 INSULIN-LIKE GROWTH FACTOR1 AS A MARKER OF SEVERITY OF LIVER CIRRHOSIS**

**Aims and Methods:** The study included 69 patients with liver cirrhosis of various etiologies from Menoufa University Hospitals (Egypt) and 18 healthy volunteers as a control group. They underwent physical examination and laboratory investigations (CBC, liver profile [ALT, AST, serum albumin, bilirubin, PT %], urea, creatinine, fasting glucose, postprandial glucose and serum IGF-1). Abdominal ultrasonography was done for all patients. Child-Pugh Score, MELD score and AST/Platelet ratio index (APRI score) were calculated for all patients.

**Results:** IGF-1 of cirrhotic patients (73.1 ± 42.3 ng/ml) was significantly lower than controls (243.2 ± 78.1 ng/ml) (p = 0.0001). IGF-1 was significantly lower in Child class C (46.11 ± 66.6 ng/ml) than Child class B (64.8 ± 44.4 ng/ml) and A (149.1 ± 43.8 ng/ml) (p = 0.002 and 0.0001 respectively). Also IGF-1 was significantly lower in Child class B than class A (p = 0.0001). IGF-1 was significantly lower in patients with MELD score < 20 (45.62 ± 6.72 ng/ml) than MELD score 10–19 (61.28 ± 13.85 ng/ml) and MELD score > 20 (152.1 ± 44.30 ng/ml) (p = 0.0001). IGF-1 was significantly lower in patients with APRI < 1.5

Introduction: Chronic HCV infection (cHCV) is a leading cause of liver disease and transplantation worldwide and a major burden on public health. Early diagnosis and classification of the degree of liver fibrosis is crucial in clinical practice to determine the urgency and need for anti-HCV antiviral therapy.

Aims and Methods: To assess the metabolites that are associated with fibrosis stages in chronic HCV infection, using metabolomic analysis.

Results: A total of 40 patients were included in the study, 30 diagnosed with cHCV infection and 10 controls. Fibrosis were assessed using FibroMax elaborated by Biopredictive (R) (Paris, France). The metabolomic techniques (high performance liquid chromatography coupled with mass spectrometry (LC-MS) and principal component analysis (PCA)) were performed from serum and urine samples of each patient, to identify final products of various metabolic pathways correlated with liver fibrosis.

Conclusion: The 30 patients with cHCV included in the study, 20 patients (66.6 %) had advanced fibrosis (F3-4). The metabolic profile identified 3 metabolites (3 of serum and 2 of urine) that are associated with severe fibrosis (F3-4): hexacosanoyl carnitine > 26416 (AUC 0.717; Se 61%, Sp 80%; p = 0.03); aspartylaspartic acid > 228956 (AUC 0.700; Se 70.00%, Sp 70.00%; p = 0.05); prostaglandin E2 (PGE2) > 4265917 (AUC 0.695; Se 65.30%, Sp 70.00%; p = 0.04) and lactic acid (a) > 70056 (AUC 0.766; Se 63.16%, Sp 100%; p = 0.003), taurine (u) > 50172 (AUC 0.772; Se 78.45%, Sp 77.78%; p = 0.008).

The combined use of the metabolites determined an AUC of 0.863, with Se 82.35 and Sp 88.80, p < 0.0001.

P0005 THE INFLUENCE OF HYPERGASTRINEMIA ON MOTILITY AND LIVER HISTOLOGICAL PECULIARITIES

A. Antonenko1, K.O. Dvorshechenko2, S. Pylypenko1, T. Beregova1, L.I. Ostapchenko3
1Bogomolets National Medical University, Department of Internal Medicine 3, Kiev, Ukraine
2Taras Shevchenko National University of Kyiv, Biology, Kyiv, Ukraine
3Poltava National V.G. Korolenko Pedagogical University, Department of Biology and Basis of Human Health, Poltava, Ukraine

Contact E-Mail Address: antonianatenenko2@gmail.com

Introduction: The influence of hypergastrinemia on the motility and liver function is not well studied. The hypochlorhydria of gastric juice can occur in the case of prolonged use of proton pump inhibitors, atrophic gastritis, autoimmune processes etc. It leads to hypergastrinemia, decrease of pepsin activation, dysbiosis, motility violation.

Aims and Methods: The aim of our work was to study histological liver peculiarities due to the influence of hypergastrinemia, to estimate the severity of inflammation and to study the role of multiprobiotic in these conditions. We included 40 rats that were randomly divided into 4 groups with 10 rats in each. Group 1 (control) received intraperitoneally 0.5 ml/kg and per os 0.5 ml of water once per day during 28 days. Group 2 received 0.14 ml/kg multiprobiotic once per day during 28 days. Group 3 received 14 mg/kg omeprazole once per day during 28 days (model of prolonged hypochlorhydria). Group 4 received 0.14 ml/kg multiprobiotic + omeprazole in dose 14 mg/kg during 28 days. Of all of them the histological peculiarities of liver were studied, we measured the levels of IL-1, IL-4, IL-6, TNF-alpha. The expression of genes Nos2, Tgfbl, ChgA, Regla, Hgf was measured using semi-quantitative reverse transcription polymerase chain reaction with densitometry.

Results: A long-term suppression of gastric acid secretion leads to the violation of motility, hypergastrinemia, that increases dysbiosis. The inflammation was absent in the group that received multiprobiotic. In the group with marked hypochlorhydria IL-1 was increased in 4.7 times (p < 0.01), IL-6 was increased in 8.1 times (p < 0.01), during the histological examination leukocytes infiltration and edema were observed. The administration of multiprobiotic led to the increase of IL-4 and IL-10 in 2.1 and 2.7 times correspondingly. It was established the increase of relative gene nitric oxide synthase 2 (NOS2) expression in the liver and pancreas. In the liver was increased the expression of transforming growth factor beta 1 (TGFβ1), chromogranin A (CHGA) and regenerating islet-derived protein 1 alpha (REG1a). The expression of hepatocyte growth factor (Hgf) was absent that indicates on violations of molecular mechanisms of the regulation of anti-bacterial processes.

Conclusion: The results of performed investigations clearly indicate the development of new mechanisms which are associated with the progression of oxidative stress in liver upon these experimental conditions. As a result of these disturbances, the damage of functional status and further possible formations of fibrosis in liver can occur. The leading role of pathogenic microbiota in violation of structural and functional state of liver upon long-term suppression of gastric acid secretion were established.

P0006 AMNION-DERIVED MESENCHYMAL STEM CELLS AMELIORATES SCLEROSING CHOLANGITIS IN RATS

Hokkaido University Graduate School of Medicine, Department of Gastroenterology and Hepatology, Sapporo, Japan

Contact E-Mail Address: ryousugira@yahoo.co.jp

Introduction: Cell therapy with mesenchymal stem cells (MSCs) is expected as a new therapeutic strategy, and large numbers of MSCs can be isolated from the amnion noninvasively. Sclerosing cholangitis is a chronic cholestatic disease, characterized by inflammation, oblitative fibrosis of bile ducts, stricture formation, progressive biliary obstruction leading to cirrhosis. Many factors are involved in the development of sclerosing cholangitis; however, the effective medical therapy for sclerosing cholangitis has not been established. Therefore, a new strategy to delay or prevent disease progression of sclerosing cholangitis is urgently required.

Aims and Methods: We investigated the effects of human amnion-derived MSCs (hAMSC) and conditioned medium (CM) obtained from hAMSC cultures in rats with sclerosing cholangitis. Sclerosing cholangitis was induced by the intra-gastric administration of 100 mg/kg alpha-naphthylisothiocyanate (ANIT) twice weekly for 4 weeks. ANIT is a toxin that targets intrahepatic bile ducts, and it is used to generate animal models of sclerosing cholangitis. hAMSCs were cultured in dishes until reaching a subconfluent state. After washing, cells were further cultured for 48 hours in serum-free medium and subsequently, CM was collected. One million hAMSCs suspended in 200 µl of phosphate-buffered saline or 200 µl of CM were intravenously injected into the penile vein on days 15 and 22. All rats were sacrificed on day 29. In each animal, the left lobes of the liver were evaluated via histological, immunohistochemical, and mRNA expression analyses.

Results: Biliary hyperplasia, peribiliary fibrosis, and inflammation in Glisson’s sheath were induced by ANIT. Histological scoring demonstrated that hAMSC transplantation and CM administration significantly suppressed biliary hyperplasia. The number of necrotic lesions was significantly decreased by hAMSC transplantation. In addition, immunohistochemical examination demonstrated that hAMSC transplantation and CM administration significantly improved...
biliary hyperplasia, peribiliary fibrosis, and inflammation in Glissonean sheath. Accordingly, mRNA expression of CK19, MMP-9, TNF-α, and MCP-1 in the liver was also significantly decreased by HAMSC transplantation and CM administration.

Conclusion: hAMSC transplantation and CM administration ameliorated biliary hyperplasia, peribiliary fibrosis, and inflammation in Glissonean sheath in a rat model of sclerosing cholangitis. hAMSCs and CM may represent new modalities for treating sclerosing cholangitis.

Contact E-Mail Address: agustin castiella@yahoo.es

Introduction: Liver steatosis is often suspected in patients with hyperferritinemia.

Aims and Methods: To study the BMI and alcohol consumption of patients referred for HF to 6 hospitals in the Basque country, Spain. To study the prevalence of hepatic steatosis determined by MRI in these patients.

A prospective study of 312 consecutive with HF (1700 men / 1420 women) and/or TSI > 20 mg/L men / 10 mg/L women, viral infection (HCV, HBV), oral iron, menopause, one or more MtS criteria (2) or BMI 25-30: 56/129 (43.41%) / 286; the results obtained were statistically significant (p = 0.000). Relationship with alcohol consumption was also evaluated. Alcohol consumption was directly related with the presence of liver steatosis: 43/196 patients (21.94%) -no alcohol-mild steatosis (59.88%), moderate/ heavy drinker. The results were statistically significant (p ≥ 0.000).

Conclusion: BMI and alcohol consume are directly related with the presence of liver steatosis in patients referred for hyperferritinemia in our country.

Introduction: The dysmetabolic syndrome with iron overload (DIOS) is characterized by producing hyperferritinemia (HF) with slight elevation of the hepatic iron concentration, together with one or more diagnostic factors of metabolic syndrome (MS): obesity, hypertension, dyslipidemia, and/or abnormal metabolism of glucose or BMI > 25 kg/m². It is associated with up to 50% with NAFLD/NASH.

The diagnosis is made discarding the usual causes of hepatic iron overload.

Aims and Methods: To study the cases of DIOS in a cohort of patients with hyperferritinemia sent to 6 hospitals in the Basque Country and to determine its relationship with mutations of the HFE gene and with hepatic steatosis.

A prospective study of consecutive patients with HF (>200 μg/L women; 300 μg/L men) and/or TSI > 45%, confirmed in 2 determinations, was conducted from December 2010 to April 2013. Dysmetabolic iron overload syndrome (DIOS) was diagnosed (1) when ≥ 36, one or more MtS criteria (2) or BMI ≥ 25; exclusion criteria: C282Y/C282Y, LIC > 80-phenotypic hemochromatosis, alcohol > 40 g/day men / > 20 g/day women, viral infection (HCV, HBV), oral iron, blood transfusions. LIC was determined by MRI 1.5 Tesla system (SIR method)

(3). We systematically performed T1-weighted in-phase and opposed-phase imaging to determine the presence or not of liver steatosis (4). We studied HFE gene mutations in all the patients.

Results: 312 patients (272 men / 40 women) were included. Mean age 55 (SD 13.5); Mean ferritin 729.6 (SD 449.6), mean TSI 40.8 (SD 15.8); 82 patients were diagnosed with DIOS. H63D/H63D 19 (23.17%), C282Y/H63D 11 (13.41%), C282Y/wt 5 (6.10%), H63D/wt 25 (30.49%). When we compared the results with those of Basque general population (5), the differences were statistically significant for H63D/H63D (p = 0.002) and C282Y/H63D (p = 0.009) mutations.

In 286 patients a MR study for the presence of liver steatosis was performed: 196 no steatosis; 90 liver steatosis (31.47%). There were 71 DIOS patients (from 82 with MR for LS determination: 13 with LS (18.31%)), 58 without LS (81.69%). From 215 patients without DIOS and with MR-77 LS (35.81%), 138 without LS (64.19%). When we compared the patients from DIOS group with MR and the group without DIOS and MR, LS was more frequent in the group without DIOS (p = 0.006).

Conclusion: HFE gene mutations H63D/H63D and C282Y/H63D are more associated with DIOS patients than with general population in our country; liver steatosis is more frequent in patients without DIOS than in patients with DIOS.

P0009 NON-ALCOHOLIC FATTY LIVER DISEASE IS ASSOCIATED WITH CORONARY ARTERY CALCIFICATION IN ASYMPTOMATIC INDIVIDUALS

K.M. Sohn1, Y. Jeon2

1Hansol Hospital, Gastroenterology, Seoul, Korea (Republic of)
2MedGene Lab., Seoul, Korea (Republic of)

Contact E-Mail Address: dr.sohnkm@gmail.com

Introduction: Nonalcoholic fatty liver disease (NAFLD) is related closely to risk factors for coronary artery disease (CAD), but it is unclear whether NAFLD independently contributes to asymptomatic individuals. Coronary artery calcium (CAC) scanning is the predictor of coronary events. We investigated the association of coronary artery calcification with NAFLD in asymptomatic adults.

Aims and Methods: This is the cross-sectional study performed in Hansol Hospital Healthcare Center. NAFLD was defined as cases with the typical ultrasonographic findings without excessive alcohol consumption, medications causing hepatic steatosis or other chronic liver diseases. CAC was evaluated using the Agatston method.

Results: We enrolled 312 subjects (mean age, 46.8 ± 8.7 years; 60.7% males) without known liver disease or a history of ischemic heart disease. NAFLD was found in 27% of the enrolled subjects and CAC > 100 with moderate-high risk of CAD was found in 10.3% of subjects. Male gender (odds ratios (OR), 2.857; 95% confidence intervals (CI), 1.169-6.147), diabetes mellitus (OR, 2.739; 95% CI, 1.092-5.638), increased age (OR, 1.288; 95% CI, 1.071-1.571), and history of hypertension (OR, 1.826; 95% CI, 1.065-3.592) were independent factors that increased the risk of CAC > 100 in binary logistic regression.

Conclusion: NAFLD is associated with increased coronary artery calcification independent of traditional risk factors. The assessment of CAC may be useful in identifying NAFLD patients at risk of future cardiovascular events even in asymptomatic individuals.

Disclosure: Nothing to disclose
A POTENTIAL LINK BETWEEN POLYCYSTIC OVARY SYNDROME AND NON-ALCOHOLIC FATTY LIVER DISEASE: AN UPDATE META-ANALYSIS

X. Wang1, J. Wu2
1Changzhou No. 2 People's Hospital, Affiliated with Nanjing Medical University, Gastroenterology, Changzhou, China
2Zhejiang No. 2 People's Hospital, Affiliated with Nanjing Medical University, Changzhou, China

Contact E-Mail Address: wxy2009@126.com

Introduction: Polycystic ovary syndrome (PCOS) itself accounts for a high risk of developing non-alcoholic fatty liver disease (NAFLD). Alternatively, other specific factors in women with PCOS may contribute to this association, which presently remains unknown.

Aims and Methods: We aimed to shed some light into this issue, and thereby performed this meta-analysis. Relevant studies that were published before May 2017 were identified and retrieving from PubMed and Web of Science databases.

Data were extracted, and the pooled odds ratios (ORs) and 95% confidence intervals (95% CIs) were calculated.

Results: A total of 17 studies were included into this analysis. Compared to the control group, the risk of NAFLD in the PCOS group was higher (OR = 2.25, 95% CI = 1.95–2.60). When stratified by BMI and geographic location, these results indicated that the frequency of NAFLD risk was significantly higher amongst obese subjects (OR = 3.01, 95% CI = 1.88–4.82), non-obese subjects (OR = 2.07, 95% CI = 1.12–3.85), subjects from Europe (OR = 2.00, 95% CI = 1.58–2.52), subjects from the Asia-Pacific Region, (OR = 2.32, 95% CI = 1.89–2.84) and subjects from America (OR = 2.96, 95% CI = 1.93–4.55), respectively. In addition, PCOS patients with hyperandrogenism (HA) had a significantly higher risk of NAFLD than controls (OR = 3.31; 95% CI = 2.58–4.24). However, there was no association between PCOS patients without HA and higher risk of NAFLD (OR = 1.46; 95% CI = 0.55–3.87).

Conclusion: In summary, women with PCOS are more likely to develop NAFLD. Furthermore, HA itself is not a major factor leading to the disease. An excess in androgen levels, which is the main feature of PCOS and is interrelated to IR, might be a contributing factor to the development of NAFLD in PCOS patients. These findings have clinical implications for NAFLD screening in hyperandrogenic women with PCOS.

UDCA EFFICACY IN THE TREATMENT OF NON-ALCOHOLIC FATTY LIVER DISEASE

I. Pirogova1, S. Yakovleva1, T. Neumayn1
1South Ural State Medical University, Chelyabinsk, Russian Federation

Contact E-Mail Address: irina.pirogova@inbox.ru

Introduction: Dyslipidemia, insulin resistance, steatosis and fibrosis play a key role in the pathogenesis of NAFLD.

Aims and Methods: We aimed to evaluate the effect of UDCA in combination with of lifestyle modification on liver steatosis and fibrosis, insulin resistance (IR) and lipid profile in these patients with NAFLD.

90 obese (BMI >30, Mediana - 32) patients (men 49) with NAFLD were included in the study. The median (Me) age - 45.6 years. All patients had cystosis (> 2 mm) and / or Fibrosis (F) and Steatosis (S) - 1 stage by FibroScan 502 TOUCH equipment. There were 40 patients for obese patients and CAP technology. Blood lipid spectrum, IR, signs of inflammation were evaluated. Body metabolism (M) assessed by method of indirect calorimetry and impedimentance (IM). It was done before treatment (0 stage) (minus 500 kcal/day with low level of carbohydrates <100g/day) in combination with exercises (plus 500 kcal/day).

63 patients were prescribed a diet in combination with daily aerobic exercise (group 2). Follow up period - 6 months.

Results: According to IM data in both groups there was a decrease in body weight (Me =7% of baseline), basal metabolism (Me =10%), fat mass in Me =14%. At the same time muscle mass increased - with a parallel increase in muscle mass- metabolically active body mass Me = 8. According to IM evaluation there was an increase in respiratory exchange ratio by 12% with an increase in oxygen consumption (+ 15%) and a decrease in the O2 production (+13) in both groups, a decrease in the metabolic age by 5 years (Me). Metabolic parameters correlated (r>0.3) with value of insulin, glucose, total cholesterol, LDL, S. F. There was a 25% decrease in Me of ALT, p < 0.01 (1st group), and 12% of the 2nd group (p < 0.05); reduction of AST by 36% and 8% respectively (p < 0.001), GGTP-36% and 27% respectively (p < 0.001), glycated Hb-20% and 11% (respectively) (p < 0.05); insulin levels 16% and 14% respectively (p < 0.02); HOMA - 16% and 8% respectively (p < 0.04); total cholesterol 10% and 5% respectively (p <0.001); triglycerides -27% and 10% respectively (p < 0.05); LDL 22% and 10% respectively (p < 0.05); S (dB/m²) -19% and 13% respectively (p < 0.05); F -reduction in 1 stage (Metavir) in 40% of patients in group 1.

Conclusion: The UDCA administration in combination with of lifestyle modification in obese patients with NAFLD results in significant reduction of liver enzymes levels, insulin resistance and dyslipidemia compared with non-pharmacological therapy only.

Introduction: Polycystic liver disease (PLD) is an inherited disorder associated with autosomal dominant inheritance. The prevalence of PLD currently consists of six genes related to autosomal dominant PLD (ADPLD) and two genes related to PLD in patients with autosomal dominant polycystic kidney disease (ADPKD). The genetic causes of PLD in the majority of ADPLD patients remains unknown. Identification of these genes is important for understanding of pathways leading to liver cysts as well as possible genotype-phenotype associations. The aim of our study was to identify novel genes associated with PLD.

Aims and Methods: We deployed molecular inversion probe (MIP) analysis for the discovery of genetic variants in 26 genes in a cohort of unrelated PLD patients. We developed probes for 5 known genes associated with PLD and 21 genes chosen for their association with liver or kidney cysts in literature. Variants identified using the MIP assay were filtered before validation using Sanger sequencing. The validated variants were then selected based on novelty or SNP frequency < 0.001, in silico prediction using bioinformatics prediction tools (PolyPhen 2, SIFT), and similarity of pathogenic variants in known PLD-genes. If available, family members were screened to test for disease segregation.

Results: We identified 625 unrelated patients with the primary phenotype of PLD. After the first filter steps of the MIP methods we identified 280 variants in 15 genes significantly associated with PLD. For six remaining genes no variants were identified that complited to all filter steps. Sanger sequencing of these 280 variants lead to validation of 85 variants in 10 genes. Sixty-five of the non-validated variants occurred in the remaining 5 genes. Of the validated variants, 49 variants and their known SNPs with frequency < 0.001 (n=36), have not been described before (n = 11), or frequency data is not available (n = 2). These 49 variants were all predicted to be likely pathogenic or pathogenic by in silico prediction and are found in 9 genes.

Conclusion: We identified 49 genetic variants in 9 genes in a large international cohort of PLD patients. These are all novel or rare variants predicted to have deleterious effect on their corresponding protein. These genes are possibly associated with PLD and are excellent candidates for further functional studies to provide evidence for their relation with PLD.

Introduction: Human liver is known as one of the target organs for estrogens, with mitogenic activity. Bisphenol A (BPA), is an artificial environmental endocrine disrupting chemicals (EDCs) that leaches from polycarbonate plastics that consequently leads to low-dose human exposure. The BPA environmental exposition was hepatic damage and worsening of non-alcoholic fatty liver disease (NAFLD). BPA is considered to be a xeno-estrogen and it can bind to estrogen receptors (ERs). Estrogens play important roles in the cell proliferation and invasion of estrogen dependent human neoplasms.

Aims and Methods: The aim of this study was to investigate the low dose of BPA effects on cell proliferation, oxidative stress and impaired synthesis of steroid hormones in human HepG2 cells. Cells were exposed to non-toxic BPA concentration (0.025 and 0.05 μM) for 48 and 72 h. Cell viability was assessed by adding 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide (MTT) assay. The level of Thioflavine T-Acidic-Resistant Species (TBARS) was assessed as markers of lipoperoxidation. The effect of BPA on the expression of p-ERK, ERK, Caspase 3 and aryl hydrocarbon receptor (AhR) was determined by Western blot analysis. The analysis of steroids extracted from cell culture medium were performed by mass spectrometer analysis.

Results: BPA was able to induce a significant increase of both cell proliferation (p = 0.0013) and TBARS concentration (p = 0.0003) after 48 hours of incubation. Moreover BPA increased the protein expression of key molecules involved in the regulation of proliferation and survival, as ER, p-ERK and AKT, and reduced the expression of caspase 3. Low dose of BPA induced an increase estrogen/testosterone ratio compared to untreated cells. The major representative peaks present in the media of BPA-treated HepG2, obtained by mass spectrometry, were: 17β-estradiol 3-sulfate (353.1 ± 1 m/z), methoxyestrone 3-sulfate (381.3 ± 1 m/z), 17- hydroxyprogesterone (331.3 ± 0.2 m/z), estrone (269 ± 1 m/z), estradiol (238.3 ± 1 m/z), testosterone sulfate (367.4 ± 1 m/z) and cholesterol (393 ± 1 m/z).

Conclusion: In the present study we demonstrated that treatment of HepG2 cells with low doses BPA elicited: 1) increase of proliferation rate; 2) regulation of oxidative stress 4) induction of oxidative metabolism of estrone.

P0015 TRANSIENT ELASTOGRAPHY, APRI AND FIB-4 SCORES FOR STAGING OF FIBROSIS AND CIRRHOSIS IN WILSON DISEASE

R. Paternostro, A. Stättermayer, M. Trauner, P. Ferenci, A. Ferlitsch
Medical University of Vienna, Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria

Contact E-Mail Address: rafael.paternostro@medunwien.ac.at

Introduction: Data on the predictive capability of cirrhosis through transient elastography (TE) in Wilson disease (WD) is scarce. Furthermore there is no data regarding its value to monitor therapy. Aim was therefore to assess whether TE is a suitable tool to identify cirrhosis in patients (ii) newly diagnosed and (ii) under treatment for WD.

Aims and Methods: Patient with WD underwent TE (results in kPa) either at the time of diagnosis or during a regular outpatient visit during treatment. Data are shown only for patients in whom a liver biopsy was available. Furthermore data on initial liver biopsy results and non-invasive fibrosis scores (APRI, FIB-4) were recorded.

Results: 35 patients were included in the study. Of those 6 were de novo patients [Male: 50%, Age: 34 ±10, TE: 10.9 kPa (3.5-34.8)], Cirrhosis at LBX: 50% and 49 patients [Male: 49%, Age: 40 ±14], TE: 7.4 kPa (3.5-15.4), Cirrhosis at LBX:36.7%] had received various length of treatment with chelators. Significantly more patients under treatment were found with TE values < 12kPa [93.6% vs. 62.5%; p = 0.009] irrespective of initial biopsy results. Moreover the APRI classification found no patients (0%) with cirrhosis in the treated group (vs. 33.3% in the no-treatment group, p<0.001). No non-cirrhotic patient worsened under treatment according to the APRI classification (cirrhosis: F3/F4).

Conclusion: TE and non-invasive fibrosis scores are valid tools to discriminate cirrhosis in newly diagnosed WD patients. In cirrhotic patients no long-term treatment TE, APRI and FIB-4 were mostly below the threshold for advanced fibrosis, indicating that decompensating therapy prevents progression of liver disease.

Introduction: A recently created ultrasonographic score (Ultrasonographic fatty liver indicator (US-FLI)) allows the grading and staging of non-alcoholic fatty liver disease (NAFLD).

Aims and Methods: We aimed to assess the correlation of US-FLI with the controlled attenuation parameter (CAP) in patients with non-alcoholic fatty liver disease (NAFLD).

Interally, inter-observer agreement for the score was assessed between 3 physicians using a sample of 31 patients. Later, 96 patients with NAFLD were included and several anthropometric, clinical and analytical parameters were assessed and US and transient elastography was performed.

Results: Physicians showed an excellent absolute agreement regarding the total score, with an average Interclass Correlation Coefficient of 0.972 (95% CI 0.949–0.986).

Patients had a medium US-FLI of 6 ± 3 points and a mean CAP of 311 ± 45 dB/m. Comparing US-FLI with CAP, and considering the previously defined cutoff for steatosis > 51 (286dB/m) and > S2 (280dB/m), we verified that US-FLI had a good discriminative capacity for both grades, with areas under the curve (AUC) of 0.88 (p < 0.001) and 0.90 (p < 0.001), respectively. We also verified that a US-FLI < 3 points had a negative predictive value of 100% for steatosis > S2 and that values of US-FLI ≥ 6 points had a positive predictive value (PPV) of 94.0% for steatosis > S2.

When comparing the clinical score Fatty Liver Index (FLI) for the same CAP cutoffs, it showed a weak discriminative capacity for both grades with AUC of 0.65 (p = 0.030) and 0.66 (p = 0.017). When comparing AUC for US-FLI and FLI scores, we verified that these were significantly different for both cutoffs (p < 0.001).

Conclusion: US-FLI has an excellent reproducibility and a good discriminative capacity for the different steatosis grades. Scores ≤ 3 points allow us to exclude significant steatosis and scores ≥ 5 points have a PPV of 94.0% for steatosis > S2.

US-FLI was significantly superior to the clinical score FLI in the discrimination between steatosis grades.

Disclosure: Nothing to disclose

P0017 IDENTIFYING THE NEXT TREATMENT FOR POLYCYSTIC LIVER DISEASE USING A DRUG SCREENING LIBRARY

L.F.M. van de Laarschot, A. van Spijk, K. van der Ende, R.H.M. Morsche, J.P.H. Dreeth
Radboud University Medical Center, Gastroenterology and Hepatology, Nijmegen, Netherlands

Contact E-Mail Address: liyanne.vandelaarschot@radboudumc.nl

Introduction: Autosomal dominant polycystic liver disease is an autosomal dominant genetic disorder caused by mutations in the genes PRKCSH, PCK1, and FLCN. The majority of patients develop cysts in the liver, which is an urgent need for a safe treatment that decreases cyst proliferation, and hence classified patients with cirrhosis, whereas in treated patients with cirrhosis at L.T. (n = 18) only 16.7%, 5.6% and 27.8% where classified with cirrhosis according to TE > 12kPa, APRI and FIB-4 scores respectively (see Table 1) suggesting a potential reveresible effect of therapy on the course of the disease.

Conclusion: In conclusion, TE and non-invasive fibrosis scores are valid tools to discriminate cirrhosis in newly diagnosed WD patients. In cirrhotic patients on long-term treatment TE, APRI and FIB-4 were mostly below the threshold for advanced fibrosis, indicating that decompensating therapy prevents progression of liver disease.

Disclosure: Nothing to disclose
cyst volume. The aim of our study is to design a diagnostic pipeline that is able to identify candidate compounds that may be involved in the pathophysiology of cysts. This pipeline involves the identification of key pathways related to hepatic cystogenesis: cell proliferation and fluid secretion caused by decreased calcium signaling and subsequently increased cAMP levels.1

**Aims and Methods:** The Selleckchem FDA-approved drug screening library contains a wide spectrum of compounds with therapeutic targets. PRKCSH knockout H69 cholangiocytes were used as in vitro model for polycystic liver disease. Cells were incubated with compounds at 10 microM concentration for 24 hours in triplicate. Proliferation was measured as absorbance after addition of WST-1 proliferation reagent (Sigma-Aldrich) for 3 hours. Compounds causing proliferation > 20% compared to DMSO controls were selected for incubation in wildtype H69 cholangiocytes. Compounds showing > 50% of proliferation compared to control and > 20% absolute difference between knock out and wildtype H69 cholangiocytes were identified as most promising. Compounds were further tested for their effect on cyclic AMP levels after 24 hours incubation using ELISA (Cayman).

**Results:** 1278 compounds showed proliferation rates of 80-120% relative to control in PRKCSH knockout H69 cholangiocytes. 26 compounds increased proliferation > 120% of control and 138 compounds decreased proliferation below 80% of control proliferation rate. These 164 compounds were further tested in wildtype H69 cholangiocytes, while octreotide was added as reference. 18 compounds showed proliferation > 50% of control proliferation rate and > 20% absolute difference between knock out and wildtype H69 cholangiocytes. These compounds were then screened for their effect on cyclic AMP levels of these compounds. We identified 3 FDA approved drugs that reduce proliferation rates in PRKCSH knockout cholangiocytes with large effect on proliferation rates in wildtype H69 cells. These drugs showed reduction of cyclic AMP as well. Target pathways of these compounds differ from somatostatin analogues and may become future pharmaceutical options for patients unresponsive to current treatment.

**Disclosure:** Nothing to disclose

Introduction: Previous large-scale genetic studies identified single nucleotide polymorphisms (SNPs) of the TM6SF2 and MBOAT7 genes as risk factors for alcoholic liver cirrhosis and non-alcoholic fatty liver disease. In this study, we tried to evaluate the role of TM6SF2 rs58542926, rs10401969 and MBOAT7 rs1069747, rs626283 SNPs are associated with the risk of hepatic fibrosis or liver cirrhosis of different aetiology in an Eastern European population.

Aims and Methods: The study was conducted at the Department of Gastroenterology, Homburg University, Sciences Hospital, and included 334 patients with liver cirrhosis, 128 patients with liver fibrosis, and 560 controls. SNPs were genotyped by quantitative PCR, with TaqMan allelic discrimination assays.

Results: Genotype distributions of TM6SF2 (rs58542926, rs10401969) and MBOAT7 (rs614738, rs626283) SNPs were in Hardy-Weinberg equilibrium. The TM6SF2 rs58542926 and rs10401969 alleles and genotypes had similar frequencies in patients with cirrhosis and cirrhosis groups (p > 0.05). The distribution of MBOAT7 rs626283 and rs641738 genotypes did not also differ between the 3 groups (p > 0.05). Overall, none of the 4 analysed SNPs (rs58542926, rs10401969, rs614738, rs626283) was associated with the presence of hepatic fibrosis or liver cirrhosis in our population.

Conclusion: Our study showed no significant associations between TM6SF2 (rs58542926, rs10401969) and MBOAT7 (rs614738, rs626283) gene polymorphisms and liver fibrosis, alcohol or hepatitis C virus-induced liver cirrhosis in an Eastern European population. Randomly assigning point to a predominant role of exogenous risk factors for disease progression in these patients.

P0021 ANTIOXIDANT PROPERTIES OF CELOCEXIB REDUCE HEPATIC VASCULAR RESISTANCE AND PORTAL PRESSURE IN CIRRHTIC RATS
Y. Tai1, J. Gao2–3, L. Zhang1, H. Tong1, S. Tang1, X. Jia1, C. Gan1, C. Tang1,2
1West China Hospital, Sichuan University, Department of Gastroenterology, Chengdu, China
2West China Hospital, Sichuan University, Division of Peptides Related with Human Diseases, State Key Laboratory of Biotherapy, Chengdu, China

Contact E-Mail Address: tycui@foxmail.com

Introduction: Increased hepatic vascular resistance (HVR) due to architectural distortion and intraparenchymal vasocostriction is the primary factor for the development of portal hypertension in liver cirrhosis. Oxidative imbalance in cirrhotic livers, by decreasing nitric oxide (NO) bioavailability, contributes to increasing HVR and portal pressure (PP). Cyclooxygenase-2 (COX-2) is up-regulated in cirrhotic livers and correlated with fibrosis degree and PP.

Aims and Methods: To investigate the antioxidant capacity of celexib, a selective COX-2 inhibitor, and its effects on intraparenchymal resistance during the development of portal hypertension in cirrhotic rats. In vivo study, peritoneal injection of thiacetamide (TAA) was employed to induce liver cirrhosis for 16 weeks. 36 male Sprague-Dawley rats were randomly assigned to the control, TAA, and TAA+celexib groups. TAA-cirrhotic rats received celexib or its vehicle by gastric gavage for last 8 weeks. PP, portal blood flow (PBf) and HVR were measured before sacrificed. Oxidative stress levels were evaluated by in situ superoxide (O2•−) detection staining and activity of superoxide dismutase (SOD), cGMP and arachidonic acid metabolisms in liver homogenate were quantitated. Hepatic expressions of pivotal molecules in NO bioavailability (cNOS, AMPK, nitrotyrosine), oxidation/antioxidation (NOX4, SOD) and COX pathway (COX-1, COX-2) were analyzed by western blot. In vitro study, the reconstituent plasmid with COX-2 or empty vector were transfected into LSECs (SK-HeP1) and hepatocytes (LO2). After treatment with PGE2, AH6809 (EP2 antagonist), U46619 (TXA2R agonist), Terutroban (TXA2R antagonist), Dorsomorphin (AMPK inhibitor) and GKT137831 (NOX4 inhibitor), NOX4 inhibitor, in situ O2•− levels and protein expressions were evaluated.

Results: Celexib administration significantly decreased PP by 22.8% (12.51±0.69 vs. 16.20±0.64 cmH2O, p < 0.05) and HVR by 31.6% (344.52±53.45 vs. 236.27±41.25, p < 0.05; 729.32±217.91 vs. 542.6±357.69, p < 0.05; 702.26±192.09 vs. 548.39±355.36, p < 0.05; 729.32±214.43 vs. 455.58±236.27, p < 0.05). The area under the curve (AUC) of W/F as predictor of in-hospital and 30-day mortality was 0.831 and 0.815, respectively, p < 0.01, not presenting values significantly higher than CP, MELD and CLIF-CAD scores. The cut-off value of W/F to predict in-hospital and 30-day mortality was 0.636. Conclusion: The W/F constitutes a mortality predictor independent of the CP, MELD and CLIF-CAD scores, identifying decompensated cirrhotic patients with poor short term prognosis. Thus, it is a promising biological marker, requiring more studies in order to be integrated into a new prognostic score.

Aims and Methods: Caco-2 - human intestinal epithelial cells were cocultured at day 6 post confluence with Escherichia coli (E. coli) and Klebsiella pneumoniae (K. pneumoniae) at MOI 0 - 10 for up to 4 hours. To clarify whether observed effects were due to living bacteria, bacterial components like lipopolysaccharide (LPS) and bacterial metabolites in form of supernatant of an E.coli overnight culture were also used for stimulation. Heat-inactivated bacteria served as reference. Changes in cell-cell-contact proteins (occludin and E-cadherin) were analyzed by Western blot and fluorescence microscopy. Moreover, effect on cell-cycle regulation was examined by flow cytometry.

Results: Bacterial stimulation of Caco-2 cells with E.coli or K. pneumoniae resulted in a G1 arrest with up to 11% more cells in Go/G1 phase compared to the unstimulated control. Coincubation with K. pneumoniae at MOI 5 resulted in a decreased production of occludin, while E.coli reduced both protein levels of occludin and E-cadherin. Bacterial metabolites in the supernatant of the over-night culture reduced protein levels around 30%, but less strong compared to LPS. However, both effects might be part of a bacterial mechanism to escape intestinal immune responses and promote bacterial translocation followed by the development of SBP.

Disclosure: Nothing to disclose.

Abstract No: P0025

OUTCOMES OF LARGE-VOLUME PARACENTESIS IN CIRRHOTIC PATIENTS WITH SPONTANEOUS BACTERIAL PERITONITIS

H.A.B. Siddiqui, S.H. Alishah, R. Azmat
1 Aga Khan University Hospital, Medicine, Karachi, Pakistan

Contact E-Mail Address: dr.hasit.siddiqui@gmail.com

Introduction: Pakistan ranks second among highest prevalent countries for chronic hepatitis C with a prevalence of 5.2%. Here we have an exponential increase in chronic liver disease patients, so burden of morbidity and mortality is high due to lack of transplant centres. Spontaneous bacterial peritonitis (SBP) occurs in 10–30% of cirrhotic patients and is associated with high mortality rate among hospitalized patients and its associated incidence of acute kidney injury (AKI) and hepatorenal syndrome (HRS). Large-volume paracentesis (LVP) decreases the burden of infective fluid. Outcomes of LVP in SBP patients has not been clearly addressed in previous studies. Furthermore, in the absence of more viable therapeutic options for preventing kidney impairment in SBP, the management really looms around time and need for renal replacement therapy (RRT). This study will assess the outcome of LVP in patients with SBP, both in terms of mortality, length of stay and effect on renal function.

Aims and Methods: This cross-sectional study was conducted in the Medicine Unit of Aga Khan University Hospital. A total of 113 patients with diagnosed SBP were assessed. Among these patients 61 underwent LVP while 51 were managed conservatively. LVP was done as per routine practice of safety and monitoring. All the patients received intravenous albumin and hydration as per protocol. Baseline and 48 hours clinical outcomes (including creatinine and ascitic fluid total leucocytes (TLC) count) were compared including a number of other parameters. The development of AKI and post-paracentesis induced cirrhotic dysfuncional (PPCD) were also assessed and model for end-stage liver disease (MELD) and Child-Turcotte-Pugh (CTP) scores were also calculated. Results: There was statistically significant improvement in post 48 hours creatinine among patients undergoing LVP (p < 0.001) whereas no significant improvement was seen in patients without LVP (p = 0.32). Similar improvements were seen for special care unit stay and total length of stay in patients with LVP, need for RRT and incidences of AKI and HRS among both groups.

Conclusion: LVP in patients with SBP translates into significantly positive outcomes in terms of length of hospital stay, special care unit stay, need for RRT and development of AKI and HRS. Hence LVP is recommended as a favoured therapeutic option.

[Outcome of LVP in SBP]

Disclosure: Nothing to disclose.
Aims and Methods: This study was conducted to verify the role of the aspartate aminotransferase-to-platelet ratio index (APRI) and fibrosis 4 (FIB-4) tests as non-invasive alternatives to liver biopsy. Our study included 757 patients with a median age of 42.6 ± 10 years. All patients underwent liver biopsy for fibrosis stage estimation, and the APRI and FIB-4 tests were performed. The liver biopsies were scored using the METAVIR system: 13 patients were F0 (1.7%), 356 (47%) were F1, 227 (30%) were F2, 160 (21%) were F3, and 1 (0.1%) was F4.

Results: For predicting fibrosis stages F≥3, APRI and FIB-4 had a specificity of 90% at cut-off values of 1.1 and 2.7, respectively, and a specificity of 95% at cut-off values of 1.44 and 3.4, respectively. The sensitivity of APRI and FIB-4 was 90% at cut-off values of 1.34 and 2.4, respectively, with an area under the receiver operating characteristic curve (AUC) of 0.663 (95% confidence interval [CI], 0.617–0.709) for APRI and 0.673 (95% CI, 0.627–0.719) for FIB-4. For predicting F≥3, APRI and FIB-4 had a specificity of 90% at cut-off values of 1.34 and 2.4, respectively, with an area under the receiver operating characteristic curve (AUC) of 0.663 (95% CI, 0.617–0.709) for APRI and 0.673 (95% CI, 0.627–0.719) for FIB-4.

Conclusion: For the non-invasive prediction of liver fibrosis stage, using higher cut-off values for APRI and FIB-4 is advised to improve the specificity.

Disclosure: Nothing to disclose

P0028 HEALTH-RELATED QUALITY OF LIFE IN PRIMARY BILIARY CIRRHOSIS

Introduction: Primary biliary cirrhosis (PBC) is a chronic autoimmune disease, characterized by progressive inflammation, destruction of intrahepatic bile ducts and cholestasis. Symptoms of PBC, especially itching and fatigue, lead to a reduction in Health-Related Quality of Life (HRQoL). HRQoL can be determined as disease-specific quality of life, and by using the anamnestic and clinical characteristics of the patients. HRQoL in patients with PBC are affected by: age, edema, diuretics, and some laboratory parameters. Significant predictor of total PBC-40 score is value of GGT (r = 0.417, p = 0.002). The score for the “Itch” domain positively correlates with the values of alkaline phosphatase increase (r = 0.29, p = 0.005) and gamma glutamyl transferase (GGT) (r = 0.303, p = 0.004) and alanine aminotransferase (ALT) (r = 0.231; p < 0.05). In patients with diagnosed liver cirrhosis, waiting for the liver transplantation, were retrospectively analyzed between 2006 and 2015 at Vilnius University Santaros Clinics. Etiology of cirrhosis, Child-Pugh classification, Model for End-Stage liver disease score, echocardiographic indicators of diastolic dysfunction, concentrations of bilirubin, creatinine and albumin, international normalization ratio were recorded. Diastolic dysfunction was divided into 3 grades by increasing severity by American Society of Echocardiography 2016 Data were analyzed by SPPS v.19. A p < 0.05 was considered as statistically significant.

Results: Final statistical analysis included 47 patients. The majority of patients were women, 27 (58.5%), patients’ mean age was 48.8 ± 1.175 years. All patients in our study had liver cirrhosis. Hepatitis C virus infection was the most common etiology of cirrhosis (38.3%). Normal diastolic function was present in 14 (30.0%), first grade dysfunction in 17 (37.2%) second grade in 16 (34.0%) and third grade in 2 (4.3%) cirrhotic patients. There was a significant relation by SPPS v.19. A p < 0.05 was considered as statistically significant.

Aims and Methods: The aim of a research was to evaluate the association between diastolic dysfunction of left ventricle and the severity of cirrhosis. 150 patients with diagnosed liver cirrhosis, waiting for the liver transplantation, were retrospectively analyzed between 2006 and 2015 at Vilnius University Santaros Clinics. Etiology of cirrhosis, Child-Pugh classification, Model for End-Stage liver disease score, echocardiographic indicators of diastolic dysfunction, concentrations of bilirubin, creatinine and albumin, international normalization ratio were recorded. Diastolic dysfunction was divided into 3 grades by increasing severity by American Society of Echocardiography 2016 Data were analyzed by SPPS v.19. A p < 0.05 was considered as statistically significant.

Results: Final statistical analysis included 47 patients. The majority of patients were women, 27 (58.5%), patients’ mean age was 48.8 ± 1.175 years. All patients in our study had liver cirrhosis. Hepatitis C virus infection was the most common etiology of cirrhosis (38.3%). Normal diastolic function was present in 14 (30.0%), first grade dysfunction in 17 (37.2%) second grade in 16 (34.0%) and third grade in 2 (4.3%) cirrhotic patients. There was a significant relation between diastolic function and age (p = 0.039; r = 0.3), Model for End-Stage liver disease (p = 0.007, r = 0.4).

Conclusion: According to the relation between diastolic dysfunction and Model for End-Stage liver disease score, we recommend cardiac assessment in patients with higher Model for End-Stage liver disease scores.

Introduction: Bleeding from ruptured esophageal varices (EV) is the most severe complication of patients with liver cirrhosis and portal hypertension. Upper endoscopy is the golden standard for diagnosis of esophageal varices. Non-invasive diagnosis of esophageal varices in cirrhotic patients is beneficial because it helps us to select the patients likely to have esophageal varices to do endoscopy for them.

Aims and Methods: The aim of this study was to assess esophageal varices by noninvasive parameters in patient with liver cirrhosis using some clinical, laboratory and ultra-sonographic parameters.

Methods: This study included 120 patients with liver cirrhosis of various etiologies from Menoufia University Hospitals (Egypt) and 20 healthy volunteers as controls. They underwent physical examination and laboratory investigations (CIR, liver profile [ALT, AST, serum albumin, bilirubin, PT %] and creatinine). Abdominal ultrasound and upper endoscopy were done for all patients. Child-Pugh score, MELD score, AST/Platelet ratio index (APRI score), Platelet count/spleen diameter ratio (PC/SD) and NIEC Index were calculated for all patients.

Results: Serum albumin at cutoff less than 3.65g/dl is significant in prediction of EV with sensitivity 70% and specificity 86.2%. Platelet count at cutoff less than 99000/mm³ is significant in prediction of EV with sensitivity 87.5% and specificity 55%. PC/SD ratio at cutoff less than 919.6 is significant in prediction of EV with sensitivity 78% and specificity 52%. NIEC Index at cutoff more than 25.4 is significant in prediction of EV with sensitivity 62.5% and specificity 90%. Prothrombin time at cutoff less than 99000/mm³ is significant in prediction of EV with sensitivity 68.8% and specificity 65%. Spleen longitudinal diameter at cutoff more than 140.5 mm is significant in prediction of EV with sensitivity 73.8% and specificity 70%. Portal vein diameter (PVD) at cutoff more than 15 mm is significant in prediction of EV with sensitivity 62.5% and specificity 90%. 90th percentile in 0.05 second is significant in prediction of EV with sensitivity 62.5% and specificity 90%. 90th percentile in 0.05 second is significant in prediction of variceal bleeding risk with sensitivity 82.5% and specificity 85%. PC/SD ratio at cutoff 851.6 is significant in prediction of variceal bleeding risk with sensitivity 45% and specificity 90%. Multiple logistic regression analysis of risk factors of development of esophageal varices revealed that serum albumin, prothrombin time, PC/SD ratio and PVD are significant predictors for development of esophageal varices.

Conclusion: Non-invasive predictors for presence of esophageal varices in patients with liver cirrhosis provide a method for selecting patients for endoscopic screening based on laboratory, clinical and ultrasonographic variables such as serum albumin, platelet count, PC/SD ratio, APRI score, SLD, PVD, prothrombin time and Child-Pugh score. Therefore, the number of unnecessary endoscopies will be reduced. NIEC Index, platelet count and PC/SD ratio can provide information help in prediction of variceal bleeding risk in patients with liver cirrhosis.

Disclosure: Nothing to disclose.
The Cox regression model gave adjusted hazard ratios (aHR) for all treatments. Explanatory co-variates were included in a time-dependent Cox regression model including; age, gender, body mass index, systolic blood pressure, estimated glomerular filtration rate, sodium, albumin, bilirubin, units of alcohol consumed per day, current number of liver admissions, cumulative number of infections, admissions and presence of renal complications. All variables were included in the model as categorical variables in order to include all patients.

**Results:** The Cox regression model gave adjusted hazard ratios (aHR) for all variables included. The variable that had the greatest impact on predicting death was sodium values less than 125mmol/L with an aHR of 3.2 (95% CI: 2.5-4.2).

Patients that were admitted for a renal complication had an increased aHR of 2.6 (95% CI: 2.1-3.3) and those with albumin < 34 g/L had an increased aHR of 2.4 (1.8-2.67). Those with bilirubin > 50 umol/L had an increased aHR to 1.74 (1.51-2.01) and those with an eGFR of 15-30 mL/min had an increased aHR of 1.64 (1.32-2.05). The model was validated using receiver operator curves (ROC) at 2, 3, 5 and 10 years following diagnosis of cirrhosis.

**Conclusion:** It was possible to build a reliable statistical model to forecast the likelihood of all-cause mortality in cirrhotic patients confirming the significance of hyponatraemia and renal dysfunction in the prognosis of patients with cirrhosis.

**P0034 SAFETY AND EFFICACY OF RIFAXIMIN IN PROPHYLAXIS OF SPONTANEOUS BACTERIAL PERITONITIS: IS THIS TIME TO ABANDON FLUOROQUINOLONES FOR PREVENTION OF SPONTANEOUS BACTERIAL PERITONITIS?: A SYSTEMATIC REVIEW**

S. Abd-Elsalam1, A. Menshawy2, A. Elgebra2
1Tanta University, Tropical Medicine Department, Tanta, Egypt
2Faculty of Medicine, Al-Azhar University, Cairo, Egypt

**Contact E-Mail Address:** sherif_tropical@yahoo.com

**Introduction:** The role of rifaximin in the prevention of spontaneous bacterial peritonitis (SBP) is not well studied.

**Aims and Methods:** The aim of this meta-analysis was to evaluate the role of rifaximin in the prevention of SBP. A computerized literature search for relevant clinical trials was conducted during August 2017. Data on Frequency of SBP, the success rate of prevention of SBP, mortality rate, hepatorenal syndrome, septic shock, hepatic encephalopathy, and GHT bleeding were extracted and pooled as risk ratio (RR) with their 95% confidence interval (CI) in a meta-analysis model. Heterogeneity was assessed by Chi-square test.

**Results:** Six studies involving 973 patients were included in the final analysis. The pooled effect estimate showed that the rifaximin plus norfloxacin group had less incidence of SBP (RR 0.58, 95% CI [0.37, 0.92], p=0.02) and hepatic encephalopathy (RR 0.38, 95% CI [0.17, 0.84], p=0.02) than the norfloxacin-based regimen group. No significant difference between rifaximin and norfloxacin in terms of the success rate of primary prevention of SBP (RR 0.95, 95% CI [0.24, 1.01], p=0.05; RR1.21, 95% CI [0.95, 1.55], p=0.13, respectively).

**Conclusion:** Based on our analysis, Rifaximin is a promising drug and appears to be a good alternative to norfloxacin in prevention of SBP.

**Disclosure:** Nothing to disclose.
Group 1 showed a trend to higher mortality rate (39.1% vs. 40%, p = 0.130). Mortality was also correlated with sepsis, bilirubin value; MELD-Na score and ECOG score (p = 0.05).

Conclusion: Cirrhotic patients present a high rate of infections and this group presents higher mortality rate. Our results suggest that PPI therapy is in fact, associated with higher risk of infection, which should lead us to be more strict in the indications of PPI's in these patients.

Disclosure: Nothing to disclose

P0038 ABCPS: A NEW SCORE PREDICTING IN-HOSPITAL MORTALITY IN CIRRHOTIC PATIENTS

3ICVS/3B's, PT Government Associate Laboratory, Braga/Guimarães, Portugal

Contact E-Mail Address: cataria_ariete@hotmail.com

Introduction: Cirrhotic patients have high rates of hospital readmissions and mortality. Recently, a new score - ABCPS - has emerged and allows predicting in-hospital mortality in cirrhotic patients. To date, there are no cut-off values defined for this score.

Aims and Methods: The aim of the study was to evaluate the power of ABCPS in predicting in-hospital mortality and to define cut-off values for this score.

Retrospective study, including patients hospitalized for compensated cirrhosis within 9 years. The ABCPS Score was calculated using the formula: 0.04 + 0.03 x albumin + 0.05 + 0.02 x Creatinin + 0.04 + 0.04 x Bilirubin + 0.05 + 0.28 x Potassium + 0.04 x 0.7 x Sodium.

Results: 362 patients included, 271 (74.9%) males with mean age of 57.4 ± 11.7 years. The majority of patients (85.9%) had alcoholic cirrhosis. Ascites was present in 80.4% patients, hepatic encephalopathy in 39.8%, acute kidney injury in 31.8%, variceal bleeding in 12.4%, spontaneous bacterial peritonitis in 28.7%, other infections in 3% and hepateno-renal syndrome in 3.6%. The mean hospitalization time was 11.7 ± 10.5 days. In-hospital mortality was found in 85 patients (23.5%). The mean value of ABCPS was 2.17 ± 1.18. The area under ROC curve (AUC) that predicts mortality for ABCPS score was 0.645 and the cut-off predictor for mortality was > 2.16 with sensitivity of 53% and specificity of 77%.

Patients with ABCPS > 2.16 presented higher mortality (39.1% vs. 16.2%, p < 0.001).

Conclusion: The ABCPS score is a tool to be used in the evaluation of cirrhotic hospitalized patients for its ability to predict in-hospital mortality. This study also allowed to determine cut-off values for this score.

P0039 VALIDATION OF EXPANDED BAVENO VI CRITERIA FOR PREDICTING ESOPHAGEAL VARICES

Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia, Portugal

Contact E-Mail Address: mafalda_m_p_sousa@hotmail.com

Introduction: According to Baveno VI, patients with chronic liver disease with platelets > 150,000 ul and liver stiffness measured by elastography < 20kPa can avoid upper endoscopy. These criteria were widely validated presenting high specificity but low sensitivity. Recently, Augustin S et al proposed expanded Baveno criteria (platelets > 110,000 ul and liver stiffness < 25).

Aims and Methods: Retrospective study of patients with chronic liver disease submitted to elastography between January 2013 and December 2015. Small varices with red wale marks or large varices were considered as high risk varices. The aim this study was to validate Baveno’s expanded criteria in our center.

Results: A total of 104 patients were included; mean age 57 years, 69% male. The etiology of chronic liver disease was hepatitis C in 80%, alcohol in 12%, hepatitis B in 4% and other causes in 5%. The prevalence of varices was 25%. Baveno’s expanded criteria had a sensitivity of 92% and a specificity of 74% for the prediction of esophageal varices (100% and 62% Baveno’s classical criteria). If we considered only high-risk varices the sensitivity of expanded criteria was 100% and specificity was 65% (100% and 50% classic criteria).

Conclusion: The expanded Baveno’s criteria present similar sensibility as classic criteria but with higher specificity. In clinical practice, it continues to correctly identify patients with varices but decreases the number of potential screening endoscopies.

Introduction: Decompensated cirrhosis patients are inherently immunocompromised and highly susceptible to bacterial infections due to translocation of gut flora and altered defense mechanisms. Healthcare-associated infections with multi-drug resistant (MDR) bacterial uropathogens in patients with cirrhosis have increased significantly over the last decades.

Aims and Methods: The aim of our study was to investigate rates of antimicrobial resistance among cirrhotic patients with hospital-acquired (HA) urinary tract infection (UTI) and to determine factors that significantly impact outcome associated with MDR infection.

Retrospective single-center surveillance analysis of microbiological isolates obtained from decompensated cirrhosis patients with HA UTI, defined as event on-set > 48 hours after admission, with pyuria and monomicrobial growth ≥ 105 CFU/ml on urine culture. Microbiological testing was performed using the Kirby-Bauer disk diffusion method. Isolated pathogens were classified as MDR if resistance ≥ 1 drug from ≥ 3 groups of antibiotics.

In vitro selection criteria were defined for empiric therapy defined failure therapy. Independent predictors for MDR UTIs were identified with multivariate logistic regression.

Results: A total of 65 patients were included in the analysis. The mean age was 60.8 ± 11.3 years (range 39-84 years), 48 (73.8%) were males. All patients had decompensated liver disease, 21 (32.3%) CP class B, and 44 (67.7%) CP class C, with a mean MELD score of 21.88 ± 6.07, and a mean CLIF-C AD score of 88.34 ± 10.26. Ascites was seen in 55 (84.6%) patients, and 32 (49.9%) had hepatic encephalopathy either at admission or during hospitalization. 15 patients (23%) had a diagnosis of DM. 33 patients (50.8%) were catheterized. Enterococcus spp was the most common pathogen (52.3%), followed by Klebsiella spp (14.4%) and Escherichia coli (9.2%). 35 (53.8%) isolates were MDR. Enterococcus spp were more commonly non-MDR (n = 22, 64.7%, p = 0.003). Enterobacteriaceae were mainly MDR strains (n=18, 81.1%, p = 0.001). VRE was isolated on 7 occasions (20.6%), and 16 of the Enterobacteriaceae isolates (72.7%) were ESBL-E. The overall resistance rates to ceftriaxone, ciprofloxacin, imipenem and meropenem were 93.1%, 80.0%, 47.2%, and 45.4%, respectively. Resistance to amikacin and gentamicin were 33.5% and 48.6%. Resistance to vancomycin and nitrofurantoin were 23.5% and 60.0%. Therapy failure was more frequent in patients with MDR UTIs (p = 0.039). In regression analysis, age > 65 years (OR 6.328, 95% CI 1.662–81.1, p = 0.001) and MDR UTI. was independent predictors for MDR UTI.

Conclusion: Increase in antimicrobial resistance to commonly used antibiotics for treatment of bacterial infections in patients with cirrhosis contributes to high mortality and morbidity associated with these infections. It emphasizes the significance of early recognition and proper management of these infections by prescribing appropriate antibiotics in order to reduce morbidity and mortality.

Introduction: Chemokines are major mediators of leukocyte trafficking into the sites of the immune response. Chemokine-induced signaling is mediated by a group of G protein-coupled receptors, They participate in defense against
microbial infection. Several functional polymorphisms of chemokine and chemokine receptor genes have been described to deregulate chemokine system and, therefore, in HCV infection it was assumed that these polymorphisms may be associated with persistence or clearance of the virus.

**Aims and Methods:** This study was performed to investigate the association of single nucleotide polymorphisms (SNPs) of chemokines and chemokine receptor with the susceptibility to HCV infection in Egyptian families.

**Methods:** A total of 3014 subjects comprising 845 Egyptian families were recruited from The Upper and Lower Egypt governorates and were classified into two groups: patients with chronic HCV (CHC), 108 subjects with spontaneous virus clearance (SC), and 1446 subjects taken as a healthy control group. All subjects were genotyped for rs13900 C/T SNP of CCL2 gene, rs817655 T/A SNP of CCL5 gene, and (rs734660 G/A, rs7199864 G/A) SNPs of CCR2 gene using allelic discrimination real time PCR (RT-PCR) technique.

**Results:** The carriage of the allele A of CCR2 rs734660 and the allele A of CCR2 rs7199864 were significantly higher in the CHC (OR = 4.03 and OR = 1.97, respectively, p < 0.0001) when compared with both SC (OR = 4.03 and OR = 1.97, respectively, p < 0.0001) and control groups (OR = 1.42 and OR = 2.13, respectively, p < 0.0001) while the carriage of allele C of CCL2 rs13900 and the allele T of CCL5 rs817655 were significantly higher in SC group when compared with both CHC (OR = 1.09 and OR = 2.24, respectively, p < 0.00001) and control group (OR = 0.65 and OR = 0.45 p < 0.00001 respectively)

**Conclusion:** Susceptibility to HCV infection is associated with A alleles of both rs734660 and rs7199864 of CCR2 gene while SC of HCV is associated with C allele of rs13900 of CCL2 gene, and T allele of rs817655 of CCL5 gene in the Egyptian families.

**Introduction:** Globally, there are 50 million infections per year from the dengue virus (DENV) spread over 100 countries. With the documented dispersion of dengue fever, physicians from temperate climates such as Europe are finding more often travelers with this infectious disease that frequently affects the liver, sometimes with major impact. Indeed, DENV has been implicated as an important cause of acute liver failure (ALF) in endemic countries. In addition, the secondary dengue mosquito, *Aedes aegypti*, which has been introduced in the Mediterranean region and the primary, *Aedes albopictus*, is on the verge of invading the southernmost parts of Europe.

**Aims and Methods:** We aimed to characterize the DENV-induced hepatic alterations and investigate and compare mimickers of acute liver injury disease.

**Results:** A retrospective study in a southern-European hospital to identify all patients with a positive IgM antibody for DENV in the last 6 years, using the laboratory data at the time of admission or first evaluation. In addition, diagnosis was further confirmed through positive DNA and/or a highly suggestive clinical picture and epidemiological context.

**Outcomes:** Of 2138 anti-DV IgM requests, we identified 1282 individuals with a positive result, including 279 under an age of 18 years old. Of the 1003 adults, 4.1% of the tested patients had hyperbilirubinemia. A higher PT on admission or first evaluation. In addition, diagnosis was further confirmed through positive DNA and/or a highly suggestive clinical picture and epidemiological context.

**Conclusion:** Nothing to disclose

**Introduction:** The special role of plasmacytoid dendritic cells (pDCs) in the immunopathogenesis of CHC puts them in the first place, not only as the main producers of IFN, but also as direct participants in the interaction between innate and acquired immune responses. Therapeutic regimens using direct-acting antiviral agents (DAAs) have revolutionized the treatment of CHC patients, but long-term interaction of the immune system with the hepatitis C virus forms a close immunological relationship in the adaptation process, which leads to a change in the functioning both at the cellular and systemic levels. Changing the cellular background of the therapy can dramatically affect the work of the immune system as a whole.

**Aims and Methods:** We examined 45 patients taking different regimens of CHC therapy. 27 of them received standard therapy and 18 people received DAAs. The amount of pDCs was determined by flow cytometry using monoclonal antibodies CD123 and CD 303.

**Results:** Quantitative indicators of pDCs have been reduced in all patients with CHC and vary depending on the type of CHC therapy. In patients treated with IFN, the absolute number of pDCs is 2 times lower (abs. ≈3.5) in comparison with the group receiving DAAs (abs. –6.2; p = 0.007). In the application of DAAs reduction of the absolute number of pDCs noted only on 4th week, whereas at the end of therapy (12 weeks - DAAs and 48 weeks - IFN) quantitative indicators pDCs did not differ (IFN: %–0.18; abs.–5.1; ADF: %–0.17, abs.–8.5; p < 0.05). According to catamnesis (patients examined after 12 months after the end of treatment CHC) pool pDCs after the use of drugs IFN was restored and did not differ from the indicators in healthy individuals (IFN: %–0.18, abs.–8.4; healthy: %–0.27, abs.–10.25; p < 0.05). The number of pDCs in DAAs as at the end of therapy, and in the history (%–0.18, abs.–9.5; p < 0.05) did not differ from those of healthy people.

**Conclusion:** pDCs values vary and depend on the type of therapy being performed. The use of DAAs leads to rapid eradication of the HC virus antigen from the body, which affects the dynamics of the pDCs pool and can lead to delayed changes in the immune system. Further observation and detailed study of this issue are needed.

**P0044 THE EFFECTIVENESS OF SOFOSBUVIR AND DACLATASVIR IN THE TREATMENT OF HEPATITIS C IN THALASSEMAIA MAJOR PATIENTS AND THEIR EFFECT ON HEMATOLOGICAL FACTORS**

J. Vafaeei1,2, F. Zamani2, H. Ajdarkoshi2, F. Safarnezhad Tameshkel2

**Contact E-Mail Address:** jvafaeei@メールアドレス.com

**Introduction:** Patients with thalassemia are at risk for infections such as Hepatitis C Virus (HCV) due to their repeated blood transfusions; meanwhile, the treatment of thalassemia patients who develop HCV infection is a controversial issue. 

**Aims and Methods:** Although the effectiveness of Direct-Acting Antivirals (DAAs) on HCV infection has been confirmed, their side-effects as well as effects on hematological factors due to the resultant need for blood transfusion remain to be further understood.

This study examined 61 patients with major beta thalassemia and HCV infection who had a history of interferon treatment failure. The patients underwent a 24-week treatment with Sofosbuvir (SOF) and Daclatasvir (DAC). To assess the response to treatment, SVR12 was used. At the end of the study, the need for blood transfusions was also assessed.

**Conclusion:** Hematocrit and platelet count in 14 days after any trip to tropics or sub tropics, taking into account that the virus frequently induces thrombocytopenia in addition to elevation of transaminases that may be very significant, prolongation of PT/INR and rarely hyperbilirubinemia. Dengue should also be considered in the differential diagnosis of acute liver failure and as an acute component of chronic liver disease, in the appropriate setting.

**Disclosure:** Nothing to disclose

**References**
patients before treatment was averaged 1.595 ± 0.65 bag per month, which
reduced to 1.1 bags after treatment (p = 0.01). This regimen did not affect
the amount of anemia in patients and did not differentiate the need for blood
transusions. The rate of hemoglobin before treatment was 9.5 ± 1.42 g/dl, which
reached 9.6 ± 1.6 g/dl after treatment (p = 0.54). Ferritin levels decreased signifi-
cantly in patients after treatment, and from 1948.08 ± 1539.54 ng/mL to
1315.73 ± 120.67 ng/mL (p = 0.001).

Conclusion: The combination of Sofosbuvir and Daclatasvir is an effective and
tolerable treatment regimen without affect the amount of anemia in patients and
did not differentiate the need for blood transfusions.

Disclosure: Nothing to disclose.

was treatment experienced with PEG-IFN and RBV. Most common associated extrahepatic malignancies are hematolymphoid, gynaecological and gastrointestinal. 7 patients had HBV coinfection and all of them received concomitant anti HBV therapy and none had HBV flare. 1/3rd of patients received cancer therapy concomitantly with anti HCV therapy. The rest were under surveillance post cancer treatment. All 38 patients had achieved ETR and SVR 12. Overall adverse event rate was 34%. Most common being anaemia requiring modification of ribavirin therapy (n=5). Other adverse events noted were skin rash, dyspepsia, nausea, occasional vomiting or constitutional symptoms, none of which required modification for either anti HCV therapy or cancer therapy. No drug-drug interaction was noted.

Conclusion: Real-life data of concomitant cancer chemotherapy and DAA is scarce. This study demonstrates that SVR rate is excellent (100%) in this cohort of patients with chronic HCV infection. Concomitant cancer therapy and DAA are safe. Adverse events are not serious among most of the patients and usually does not mandates cessation of either cancer or HCV therapy. 90% of patients could tolerate full dose of RBV.

Disclosure: Nothing to disclose

Aims and Methods: The aim was to investigate the difference in expression levels of circulating miR-122 in HCV-related cirrhotic patients with and without hepatocellular carcinoma (HCC). We included 41 HCV-related cirrhotic patients recruited from Ain Shams University hospitals’ clinics and in-patient department. Patients were divided into 2 groups: I) non-HCC group of 14 patients with different Child-Turcotte-Pugh (CTP) classes, II) HCV-related HCC group of 27 patients having different patterns of tumor aggression - classified using CT/MRI imaging features into low and high aggressive HCC patterns, defined as: a) Low aggression/ small sized focal HCC – single lesion < 2 cm or ≤ 3 nodules < 3 cm each, b) High aggression patterns either multicentric HCC (> coexisting 3 nodules) or infiltrative HCC (ill-defined large sized HCC with no focal mass formation).

Patients with chronic HCV infection can be cured of their disease.

**Introduction:**

Aims and Methods:

Before the start of antiviral therapy. For breast cancers no time limit was

2015 to January 2017 with solid non-hepatic tumor diagnosed in the 5 years

neoplasia in consecutive HCV patients treated with DAA.

Aims and Methods:

Results:

According to the manufacturer's instructions (Lymphoflot, Biotest,Dreieich,

obtained using Ficoll-Hypaque density gradient of EDTA anticoagulated blood

Interferon/ribavirin regimen. All patients were HCV genotype 4, compensated

January 2017 to August 2017 post Sofosbuvir 400mg/ Daclatasvir 60mg for 12

achieved SVR after sofosbuvir/daclatasvir therapy and to determine the different

Occult hepatitis C infection post DAAs therapy is not uncommon

Conclusion:

Aim was to evaluate the recurrence rate of non-hepatic neoplasia in consecutive HCV patients treated with DAA.

We included all consecutive HCV patients treated with DAA from February 2015 to January 2017 with solid non-hepatic tumor diagnosed in the 5 years

before the start of antiviral therapy. For breast cancers no time limit was

fixed. Patients with hematological malignancies were excluded. All tumors had

standard complete control before starting DAA therapy.

Results: 313 HCV patients were treated with DAA and 20 (6.4%) had a positive

anamnesis for solid non-hepatic tumor. 6 patients had a history of breast cancer,

4 gastrointestinal tumors, 2 non-melanoma skin cancer, 5 uro-genital cancers, 1

spinosocellular carcinoma of the oral cavity, 1 pituitary and 1 lung tumor. Median
time from cancer diagnosis to DAA was 3.7 years and patients were followed-up

for a median of 22.38 months after DAA therapy. No patient underwent DAA treatment concomitantly with chemotherapy. Median age at DAA therapy was

9 years and patients were men. 65% were genotype 1, 15% genotype 2, 10%

genotype 3 and 10% genotype 4. 70% had evidence of cirrhosis, well compen-
sated in everyone (CPT score A). An SVR was achieved in 19 patients (95%), and

no serious adverse events were reported. During a median of 22.38 months after

DAA therapy no patient included in the study had cancer recurrence.

Conclusion: HCV treatment in patients with solid non-hepatic tumors is safe and

effective. Although findings are preliminary, an SVR to DAA therapy was not

associated with any case of tumor recurrence.

Disclosure: Nothing to disclose.

**P0051 DO WE SCREEN HEPATITIS C BEFORE SURGERY FOR THE

BENEFIT OF THE SURGEON OR FOR THE PATIENT?**

I. Gulturk, K. Bal, I. Hatiemi, B. Kocazeybek, P. Yuksel, B. Demir, E. Karabalut

Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Introduction: The success rate of current treatments of hepatitis C infection now

approaches 100%. Therefore, it is important to conduct community screenings

and raise awareness. Pre-operative hepatitis serology is routinely considered in

most countries of the World.

Aims and Methods: We aimed to detect the prevalence of anti-HCV and HCV-

RNA positivity rate in patients undergoing pre-operative HCV screening and also

the awareness rate of having chronic hepatitis C infection in these patients. Patients who had pre-operative anti-HCV testing in surgical clinics of our hos-

pital were screened from 2013 to 2017. All patients who were positive were

questioned for HCV-RNA positivity and whether they were treated for hepatitis

C. Hospital records were screened for HCV-RNA results. Treatments reports

were reached through the integrated database system of social security with our

hospital. HCV-RNA untied patients were called by phone and asked whether they

were aware of being anti-HCV positive.

Results: During 5 years, 21897 patients were screened for hepatitis C. A total of

125 patients (0.57 %) were found to be positive (58M, 67F, mean age 59.1± 15.7)

HCV-RNA was tested in 76 of these patients, 22 HCV- RNA nega-
tive(29%), 24 were positive and treatment-naive, 19 were positive and treatment

experienced. From 125 patients with Anti-HCV positivity, 49 patients had no

HCV-RNA assay (39%), we called them by phone and noticed that just 5 (10 %)

patients knew that he/she was anti-HCV positive.

Conclusion: Anti-HCV positivity was detected in approximately 0.6% of 21897

patients who were operated in surgical departments of a tertiary medical center.

Approximately 40% were not tested for HCV - RNA and most of these patients

were not aware of being Anti-HCV positive. Testing hepatitis C serology before

surgery seems that do not contribute to catch new patients. Surgeons need to be

more aware towards chronic hepatitis C infection.

Disclosure: Nothing to disclose.

**P0052 PREVALENCE OF HEPATO-BILARY MANIFESTATION IN

IBD**

Introduction: The IBD are frequently associated to the extra intestinal manifesta-
tion: dermatologic, ophthalmic, hepato-biliary. We observed a high prevalence of

hepato-biliary manifestation in IBD (up to 50%) and one of the most serious

complication is PSC. We also noted various pathogenicities of these hepato-biliary

abnormality; the common pathogenesis of IBD, direct or indirect complication of

IBD.

Aims and Methods: The aim of our study is, first of all, to assess the frequency of

hepato-biliary manifestation on the IBD, and secondly to study clinical, advance-

ment characteristics of IBD and liver disease occurrence. In our study, we have

removed the abnormal transient liver test and the drug which caused hepatitis.

This retrospective study concerned the population with IBD of the occurrence’s

liver disease during period: 2000 - 2013. Initially, all the patients get a clinical,
biological and morphological investigation, and also a clinical, biological and

diagnostic laboratory investigation.
Results: We observed 868 patients with IBD: 459 Crohn’s disease and 277 ulcerative colitis with a median age of 42.5 years (24-81 years). During the follow-up, we noted 3.2% liver disease, among them: 13 cases of Crohn’s disease (8 male - 5 female), 9 cases of ulcerative colitis (6 male-3 female). 18 cases of liver disease was reveal by abnormal liver test, 3 cases by portal hypertension, and one by jaundice. All the investigation were determined 14 PSC, 3 steatosis, 1 peliosis, 1 overlap syndrome (HAI + PSC). Clinical and morphological characteristic study revealed that hepatobiliary manifestation are more common for male patient and also in ileo-colonic, pan-colitis forms. The IBD is the most of the time presentation of the growing period of the liver disease.

Conclusion: The hepatobiliary manifestation are rare, they are generally revealed by abnormal liver test which occurred the most often on long lasting and exten- sive IBD and PSC represented the most frequent etiology.

P0054 DEVIATIONS IN PERIPHERAL BLOOD SUBPOPULATIONS ARE CONNECTED WITH THE PRESENCE OF PRURITUS IN PRIMARY BILIARY CHOLANGITIS PATIENTS

A. Michalak1, H. Cichoń-Lach1, A. Kowalik1, E. Grywalska2, J. Rolinski3, B. Kasztelan-Szczerbinska1

Contact E-Mail Address: lady.agatamichalka@gmail.com

Introduction: Primary biliary cholangitis (PBC) constitutes an autoimmune liver disease characterized by progressive destruction of small- and medium-sized intrahepatic bile ducts. The role of particular peripheral blood (PB) subpopula- tions in the course of PBC remains uncertain. Bile acids, including deoxycholic acid and glycocholic acid, are known to induce a peripheral immune response.

Aims and Methods: The aim of our study was to assess the relationships between analyzed peripheral blood cell subsets and the presence of pruritus in patients with newly diagnosed PBC. The frequencies of PB subpopulations were mea- sured by flow cytometry in 34 previously untreated female patients with PBC. 19 participants from research group presented pruritus. The control group consisted of 20 healthy age- and sex-matched volunteers. The diagnosis of PBC was based on the commonly known criteria. The severity of pruritus was assessed according to Visual Analogue Scale (VAS) questionnaire and the mean result was 41.10 points. The degree of severity of PBC was evaluated by histologic stages of PBC. This parameter was described in all patients and they were divided into 4 groups, according to histologic stages of PBC (1 - portal stage - 7 patients, II - portal stage + 6 patients, III - septal stage - 3 patients and IV - cirrhotic stage - 2 patients).

Results: There were significant differences in CD4+ T lymphocytes and absolute counts of CD4+/CD3+ cells between research and control group (p < 0.01). There were no significant differences in percentages of CD3+/CD4+, percentages of CD3+/CD8+ and absolute counts of CD4+/CD3+ cells between research and control group.

Conclusion: The results obtained in our survey suggest that deviations in PB subgroups might be involved in the pathogenesis of cholestatic pruritus in PBC patients. This issue should be undoubtedly clarified in further studies.

Disclosure: Nothing to disclose.

P0055 A NOVEL UK REGIONAL REAL-WORLD REGISTRY FOR PRIMARY BILIARY CHOLANGITIS (PBC) ALLOWING DATA LINKAGE FROM PRIMARY AND SECONDARY CARE

M. Percioul1, C. Kelly1, S. de Luissignan2, A. Alia1,2
1Royal Surrey County Hospital, Department of Gastroenterology & Hepatology, Guildford, Surrey, United Kingdom
2University of Surrey, Department of Clinical and Experimental Medicine, Guildford, Surrey, United Kingdom

Contact E-Mail Address: perichoumarinos@gmail.com

Introduction: PBC is a model of chronic liver disease affecting approximately 35/100,000 population. Data for PBC and rare diseases appears scarce, fragmented. Coordinated efforts are required to bring various datasets together to provide integrated care for patients. A real-world registry linking primary and secondary care for PBC does not exist.

Aims and Methods: Following ethical approval, a regional observational feas- ibility study was set up collecting data from 3 regional hospitals and 10 primary care providers (General Practice surgeries) in the region of Surrey South East England which has a population of 1.1 million. From primary care providers data collected using READ codes and 725 data points were collected for each patient. In secondary care, data was collected from multiple sources including histology, fibroscan, immunology, biochemistry, virology, endoscopy, patient workflow systems, patient notes/letters, radiology and hospital coding departments. A total of 286 data points were collected for each patient. The datasets from primary and secondary care were linked for each patient using a unique patient identifier (NHS number) which was hashed using a pseudonymisation algorithm.

Results: A total of 375 patients with confirmed PBC were identified and primary and secondary care giving a regional PBC prevalence of 34.1/100,000 population. All patients from primary care were successfully linked to secondary care providing a holistic overview of the patients’ journey and the disease’s natural history.
Conclusion: Our novel method of establishing a rare disease registry for PBC is able to link datasets from various sources which are otherwise found disjointed in silos. Our registry is collecting more data points than existing PBC registries and does not rely on manual data entry from time-stretched clinicians and nurses which can affect data quality and lead to errors. This robust methodology has enabled a worldwide data on a large number of PBC patients and better understand the natural history and regional impact of this rare condition. Moreover, it will inform the development of regional frameworks for integrated care which are currently lacking for PBC and for rare liver diseases. This work will complement the efforts of larger consortia including UK-PBC and GlobalPBC.

Introduction: At present, many studies are still controversial for the response of acute presentation-AIH (A-AIH) after immunosuppressive treatment. Some studies reported that A-AIH had a worse response than chronic AIH (C-AIH) due to its more severe liver injury.

Aims and Methods: Our study analyzed the effectiveness of standard treatment (corticosteroids alone or combined with azathioprine) between A-AIH and C-AIH. First, we collected patients prospectively according to the International Autoimmune Hepatitis Group (IAIHG) revised score and the experience of hepatologists. Patients who had a probable diagnosis (IAIHG score ≥10) of AIH were included in our study. And all of these patients were treated with standard treatment. Patients who were concurrent with other liver diseases or used other immunosuppressive agents were excluded. Then, all the patients were divided into the A-AIH group and the C-AIH group. Patients in A-AIH group needed to meet at least 1 of the following conditions: (1) total bilirubin ≥5mg/dL, (2) alanineaminotransferase >10 upper limits of normal (ULN), or (3) aspartate transaminase >10 ULN. Finally, the complete biochemical remission rate, time of reaching complete biochemical remission and mortality of the 2 groups were retrospectively analyzed.

Results: 88 patients were included in our study, of which 48 patients were in the A-AIH group and 40 patients in the C-AIH group. The follow-up period was 0.3–33.1 months. There was no statistical difference in the rates of complete biochemical remission between A-AIH group and C-AIH group (50%, 35%, p = 0.55). The median time of reaching complete biochemical remission was 3.2 (1.3, 9.2) months in A-AIH group, while that in the C-AIH group was 2.4 (1.3, 4.6) months, and there was still no significant difference (p = 0.474). During the follow-up, 9 patients were dead owing to hepatic decompensation, of which 5 (10.4%) patients were C-AIH and 4 (10%) patients were C-AIH (p = 1.000).

Conclusion: Although the serum bilirubin and aminotransferase were obviously increased in A-AIH patients, the response after standard treatment of A-AIH may not be significantly different from that of C-AIH. Moreover, the different level of serum biochemical indicators may not be the most important factor influenced prognosis for neither A-AIH or C-AIH.

Disclosure: Nothing to disclose.

P0057 URSEDOXOXYCHOLIC ACID FOR THE TREATMENT OF PRIMARY BILIARY CIRRHOSIS/CHOLANGITIS AND PRIMARY SCLEROSING CHolangitis: ARE OUR PATIENTS UNDERDOSED?

Y. Abbey, M. Olsen, M. Farrant, A.V. Gunasekera
Ashford and St Peter’s Hospitals NHS Foundation Trust, Gastroenterology, Chertsey, United Kingdom

Contact E-Mail Address: yvronneabbey@doctors.org.uk

Introduction: Ursodeoxycholic Acid (UDCA) is used to treat the cholestatic liver diseases primary biliary cirrhosis/cholangitis (PBC) and primary sclerosing cholangitis (PSC). Current guidance states an optimum dose of UDCA is 13–15mg/kg in 2 divided doses, with the same dose used but not specifically recommended in PSC. A survey undertaken by the PBC Foundation in 2013 implied a third of patients were underdosed. Optimal dosing of UDCA leads to improved biochemical reponses in both PBC and PSC patients, and delayed disease progression and reduced transplant rates in PBC.

Aims and Methods: The objective of this study was to assess whether locally, our patients are optimally dosed on UDCA (using the upper end 15mg/kg) and whether this has had any impact on their biochemical response to treatment.

A database of outpatient correspondence was searched for the terms “primary biliary cirrhosis” and “primary sclerosing cholangitis”. 85 patients were identified with a confirmed diagnosis of PBC or PSC (antibody positive or biopsy proven). 7 patients were excluded from the study as they had not yet commenced on UDCA, leaving 78 treated patients (59 PBC, 19 PSC). Using the most recently documented weight around time of diagnosis/commencement of treatment, optimum doses of 15mg/kg were calculated for each patient and compared to the actual dose prescribed. Biochemical response was assessed using the Barcelona Criteria - either greater than 40% reduction in alkaline phosphatase (ALP) or normal after 1 year of UDCA treatment.

Results: Of the 78 patients, 33 (42%) were found to be at least optimally dosed at 15mg/kg, with 45 patients (58%) underdosed on UDCA. In the optimally dosed group, 19 patients (38%) showed a biochemical response, whereas 9 patients (27%) had a worsening of their ALP (1 identified as non-compliant). The remaining 5 patients (15%) had a normal ALP at the time of commencing, which remained normal to date.

In the suboptimally dosed group, 20 patients (44%) showed biochemical response, with 16 patients (36%) having a worsening in their ALP and 9 patients (20%) having a normal ALP at diagnosis which again remained normal to date.

Aims of patients with PBC responded to UDCA compared to 53% of those with PSC.

Conclusion: This study shows that a higher proportion of our local patient group diagnosed with PBC or PSC are underdosed with UDCA than optimally dosed. We have demonstrated in this group that UDCA appears effective in improving biochemical response to treatment or at least maintaining a normal ALP, when used at the optimum dose, supporting a drive towards ensuring patients are prescribed 15mg/kg of UDCA. Interestingly there was still a partial response to treatment despite underdosing all patients who had normal ALP maintained this regardless of UDCA dose. This may generally imply efficacy of UDCA in the treatment of PBC and PSC. Looking at potential reasons for underdosing, it was identified in some cases that patients’ weight had changed (markedly decreased) but not led to a subsequent adjustment of UDCA dose.

Introduction: Examination of vascular structures and flow dynamics is important in order to differentiate benign from malignant focal liver lesions (FLL). Diagnostic ultrasound in combination with contrast-enhanced ultrasound (CEUS) has a high accuracy and diagnostic value for FLL (1, 2). CEUS ideally allows the visualization of the very specific spoke wheel pattern in the arterial phase and is standard of reference (SOR) in the diagnosis of FNH smaller 3 cm (3). Conventional colour Doppler has limitations in visualizing microvascularity and low velocity blood flow. Superb Micro-Vascular Imaging (SMI) is a novel ultrasound Doppler technique with high resolution imaging, minimal motion artefacts and high frame rates. SMI has not been studied in FNH lesions, which have a unique vascular supply that is diverse in most cases. Diagnosis of this benign FLL is important to avoid unnecessary biopsies and surgical procedures. In contrast to hepatocellular adenoma, the management of FNH is conservative because there is no risk of malignant transformation, no risk of bleeding and no need to stop contraception (4,5).

Aims and Methods: The diagnostic value of the novel SMI technique for diagnosing FNH lesions in comparison to CEUS was studied. SMI offers a unique algorithm allowing visualization of microvascularity with low velocity flow with use of a novel contrast agent and analysis of flow direction and velocity to provide new adaptive algorithm to identify and remove tissue motion and reveal true blood flow. CEUS was performed as standard of reference by using 1.5 ml intravenously injected contrast agent (sulphur hexafluoride microbubbles) and was performed according to international guidelines (1). Representative still images and video clips were recorded.

Results: We present a case series of 5 female patients between 25 and 55 years with FNH. CEUS revealed in almost all cases FNH with typical early centrifugal arterial spoke-wheel enhancement without washout up to 5 minutes after injection of the contrast agent. We could demonstrate the excellent diagnostic value of CEUS.
the spoke-wheel-like vessels by SMI (without contrast agent and independently to time course). SOB was resuscitation (n = 2), MRI (n = 1) and follow-up 12–18 months (n = 2).

Conclusion: FHN is the second most common benign liver tumor after hemangioma. FHN is diagnosed by CEUS, CT or MRI using intravenous contrast agents. This is the first European experience demonstrating the excellent clinical value of SMI to diagnose typical FHN with spoke-wheel-like vessels. SMI is an easy to use, intuitive imaging tool without the need of contrast agent that offers a detailed visualization of small, low-velocity vessels within FHN lesions. In the prospective phase, it will be possible to provide this non-invasive imaging criteria for FHN as CEUS in the arterial phase. In contrast to SMI, CEUS and especially CT and MRI require early arterial contrast enhancement, which may be missed due to a short detection period of sometimes only a few seconds.

Contact E-Mail Address: ccxenli@163.com

Introduction: Noninvasive methods have been used for the assessment of hepatic steatosis in patients with nonalcoholic fatty liver disease (NAFLD). Magnetic resonance derived measures, such as proton density fat fraction (PDFF) and fat fraction (FF), and transient elastography based controlled attenuation parameter (CAP) of liver fat and volume are emerging as non-invasive, accurate imaging biomarkers.

Aims and Methods: We performed this systematic review and meta-analysis to compare the efficacies and accuracies between magnetic resonance technique and transient elastography for evaluation of hepatic steatosis in NAFLD patients. PubMed, the Cochrane Library, Embase and Web of Science were searched to gather studies, relating to accuracies of MR technique or TE for evaluating grading of steatosis (S0-S3) diagnosed by liver biopsy. We compared the sensitivity, specificity, positive likelihood ratio, negative likelihood ratio and hierarchical plot comparing the accuracies of grading of steatosis (S0-S3) using ROC curves for the studies. The clinical utilities of MR technique and TE were also evaluated.

Results: 19 articles with a total of 1558 NAFLD subjects were included. As for diagnostic accuracy of MR based PDFF, the summary sensitivities and specificities values were 0.92 (95% CI, 0.88–0.95) and 0.93 (95% CI, 0.88–0.97) for S1, 0.76 (95% CI, 0.71–0.80) and 0.88 (95% CI, 0.84–0.91) for S2, and 0.73 (95% CI, 0.68–0.78) and 0.89 (95% CI, 0.86–0.92) for S3. The HRSCs were 0.96 for ≥S1, 0.91 for ≥S2, and 0.89 for ≥S3. Following a positive measurement (over the threshold value) for ≥S1, ≥S2, and ≥S3, the corresponding post-test probabilities for the presence of steatosis (pretest probability was 50%) were 93%, 87% and 87%, respectively; if the values were below these thresholds (negative results), the post-test probabilities were 14%, 7%, and 7%, respectively. The diagnostic accuracy of MR based fat fraction (FF) for stage ≥S1, the summary sensitivity was 0.92 (95% CI, 0.87–0.95), and the specificity was 0.92 (95% CI, 0.87–0.97). Besides, the HRSOC is 0.9260. For diagnostic accuracy of TE-CAP detecting stage ≥S1, ≥S2, ≥S3, the summary sensitivity was 0.79 (95% CI, 0.67–0.89), 0.80 (95% CI, 0.75–0.84), 0.81 (95% CI, 0.78–0.84), and the specificity was 0.83 (95% CI, 0.80–0.96), 0.74 (95% CI, 0.70–0.78), 0.66 (95% CI, 0.59–0.73), respectively. Following a positive measurement (over the threshold value) for ≥S1, ≥S2, and ≥S3, the corresponding post-test probabilities for the presence of steatosis (pretest probability was 50%) were 86%, 76% and 71%, respectively, if the values were below these thresholds (negative results), the post-test probabilities were 16%, 18%, and 18%, respectively.

Conclusion: MR technique and TE both provide standardized non-invasive approaches for staging hepatic steatosis in NAFLD patients. Compared with TE based CAP, MRI derived PDFF is significantly more accurate for evaluating different grades of steatosis, especially in those obese patients, which probably offer the best diagnostic performance and may be used instead of invasive liver biopsies.

Introduction: Many complications can occur during Transjugular Intrahepatic Portosystemic Shunt (TIPS) implantation procedure. However, the most relevant clinical complication is hepatic encephalopathy (HE).
Aims and Methods: The aim of this study was to assess TIPS indications, success rates and related complications. The secondary goal was to identify predictive factors of HE after TIPS.
Results: We present a retrospecitive unicenter cohort study from October 2007 to January 2018 including patients undergoing TIPS procedure on a Portuguese referral center. Portal pressure gradients before and after TIPS were only recorded of Gastroenterology of SCJUT between January 2017-December 2017: 23 men (10.6 vs 5.9, p = 0.011). Mean AFP level was 0.56 (0.56%) and anestesia complications (0.56%).
Patients with upper gastrointestinal bleeding (11.1%), hepatic hydrothorax (0.56%) and Budd-Chiari syndrome (0.56%). 17.2% of the patients had more than 1 indication for TIPS procedure.
Technical success rate was 91.67% (n = 165). Hemodynamic success rate (since January 2015) was 82.86% in patients with refractory ascites and 100% in patients with uncontrolled gastrointestinal bleeding. 3.33% had immediate TIPS-related complications: hemoperitoneum (1.11%), haemorrhagic shock (0.56%), porto-biliary fistula (0.56%); cerebral haemotoma (0.56%) and anesthesia complications (0.56%).
After TIPS, 44.49% (n = 89) patients with refractory ascites had improved and 5.56% (n = 10) patients had a rebounding episode. HE after TIPS was seen in 44.4% (n = 80) of the patients (26.7% newly installed, 13.3% maintained and 4.4% worsened). It was found that patients with HE “de novo” or worsened were older (58.2 vs 53.6, p = 0.09). Higher severity scores (MELD and Child-Turcotte-Pugh) and non-sclerosis hernostasis were not associated with a higher occurrence of HE (p>0.05).
However, a portal pressure gradient ≥5mmHg demonstrated a higher risk of HE (OR 10.16 VS 13.45, p = 0.017).
Conclusion: The success rates were over 80%. HE was a frequent complication. Oder age and portal pressure gradient ≤5mmHg were associated with a higher risk of HE after TIPS.

2 Agrippa Ionescu Clinical Emergency Hospital, Gastroenterology and Hepatology, Bucharest, Romania
Contact E-Mail Address: mariachi_med@yahoo.com
Introduction: Sarcopenia may affect patients with liver cirrhosis. It is associated with a poorer quality of life and higher morbidity and mortality.
Aims and Methods: We aimed to evaluate the value of ultrasound measured psoas major (PM) and rectus abdominis (RA) thickness in predicting survival of patients with liver cirrhosis. 61 patients were included in a prospective study in a 16-month period and followed-up for at least 6 months. Sarcopenia was assessed using surrogate parameters: hand grip strength (HGS), mid-arm muscle circumference (MAMC) and SGA (subjective global assessment) score.
Results: There were 40 men, with a mean age of 58.03 ± 10.8 years. 26.22% of patients were Child-Pugh A, 44.59% B and 27.86% C. Patients were followed-up for 11.9 ± 5.63 months.
Mean RA (mRA) was 8.73 ± 2.57mm. RA thickness moderately correlated with MAMC (r = 0.596, p < 0.0001) and HGS (r = 0.515, p < 0.0001) and decreased with increasing SGA class (A 10.6 ± 2.86mm, B 8.3 ± 1.9mm, C 6.5 ± 1.9mm, p < 0.0001).
Survival at 6 months was independently predicted by MELD-Na score (OR 1.305, p = 0.005). Survival during follow-up was independently predicted by mRA (HR 0.701, p = 0.011, AUROC 0.732) and ascites (HR 1.876, p = 0.026, AUROC 0.732). A cut-off of mRA less than 6.75mm had 50% sensitivity and 93% specificity to predict mortality in patients with liver cirrhosis.
Conclusion: As a surrogate marker of sarcopenia, ultrasound measured rectus abdomins muscle may predict survival in patients with liver cirrhosis.

Introduction: Several studies showed that VTQ (Virtual Touch Quantification) provides additional information regarding FLLs stiffness and it is useful when disease is among malignant and benign FLLs.
Aims and Methods: We aimed to evaluate interobserver reproducibility of a point shear wave elastography- pSWE [using Acoustic Radiation Force Impulse Quantification (ARFI)]- VTQ (Siemens) for the evaluation of focal liver lesions stiffness. We performed a prospective study including 44 patients diagnosed with focal liver lesions (FLLs) after an ultrasound examination admitted to the Department of Gastroenterology of SCJUT between January 2017-December 2017: 23 men (52.3%) and 21 women (47.7%), mean age 65.3 ± 11.1 years. A total of 48 FLLs were examined.
Elastographic measurements (EM) were obtained in 48 FLLs using VTQ (Siemens). 2 examiners with different levels of experience in ultrasound-based elastography- pSWE performed VTQ on each subject: 10 measurements in the liver parenchyma and 10 measurements in each focal liver lesion. Medians and interquartile ranges (IQRs) were calculated (m/s). We used the interclass correlation coefficient (ICC) with 95% lower and upper limits of agreement (LOA) to assess the inter-observer reproducibility of VTQ.
Results: A total of 48 lesions were evaluated. The lesions were: 32.48 (72.7%) hepatocellular carcinomas, 7.48 (14.5%) hemangiomas, and 9.48 (18.7%) metastases. The total mean values obtained were: 1.62 m/s in HCCs, 2 m/s in hemangiomas and 2.62 m/s in metastases. The agreement between the novice and the experienced examiner was excellent: 0.95 (95% CI: 0.91-0.97).
Conclusion: The excellent ICCs for the median values show that ARFI technique was good for evaluating FLL stiffness is a reproducible method and could provide significant complementary information regarding the tissue stiffness, useful for the differential diagnosis of focal solid liver lesions.

Introduction: Prevalence of type II diabetes has significantly increased in the last decade. Type II diabetes and nonalcoholic fatty liver disease (NAFLD) are frequently associated.
Aims and Methods: The aim of the present study was to assess the severity of liver fibrosis and steatosis in a cohort of type II diabetic patients, using non-invasive methods: Transient Elastography (TE) and Controlled Attenuation Parameter (CAP) before and after the CAP adjustment algorithm was applied. The study included 576 type II diabetic patients, who were prospectively randomized. All were evaluated by means of TE and CAP (FibroScan EchoSens). A cut-off value of 10.5 kPa [1] was used to define clinically relevant fibrosis (F ≥ 3). We used the following cut-off values [2]: for S2 (moderate steatosis) - 255 dB/m, and 290 dB/m for S3 (severe steatosis) - We corrected the CAP values according to the presence of diabetes (we deducted 10 dB/m) and according to the degree of obesity (we deducted 4.4 dB/m for each BMI > 25 kg/m2 and added 4.4 dB/m for each BMI > 25 kg/m2) [1, 3].
Results: Out of 576 diabetes screened, we excluded those with associated viral hepatitis, those with an AUDIT-C score ≥8 and those with unreliable LSM. The final analysis included 403 subjects (59.3% women, BMI = 31.6 ± 6 kg/m2) with reliable LSM obtained using both probes. Moderate and severe steatosis by means of LSM was found in 18.9% and 61.5% cases respectively. After correction, we found moderate steatosis in 22.1% cases and severe steatosis in 52.6%
cases. We found no significant differences regarding the proportion of patients with moderate steatosis after the algorithm was applied (18.9 vs. 40.0%, p = 0.26), but we found significant differences regarding the proportion of severe steatosis, (61.5% vs. 52.6%, p = 0.01). Clinically relevant fibrosis was detected by means of TE in 13.6% (55403) of subjects.

Conclusion: In type 2 diabetes patients it is necessary to use an algorithm for correction in order to avoid overestimation of the degree of steatosis and fibrosis.

Contact E-Mail Address: elsharawy.omar@stadtmission-hd.de

**Introduction:** ALBI score eliminates the need for the subjective variables required in the CTP grade. The addition of tumor characteristics from TNM classification resulted in ALBI-T score. ALBI grade 2 showed a wide range of patients, Osagusawa sub-classification of ALBI grade 2 classes patients more precisely.

**Aims and Methods:** We accrued data from the HCC clinic at National Liver Institute, Menoufia University. We had access to a data set of a cohort of 1910 patients diagnosed with HCC and fulfilled the inclusion criteria. Patients were followed up to the time of diagnosis of time of death or date of data collection if they remained alive. Modified ALBI-T was obtained through using new grading of ALBI score (grade 1 to 4 instead of grade 1 to 3) obtained through Osagusawa sub-classification of ALBI grade 2 and using it in calculating ALBI-T score. We compared our score to other scoring systems as CTP, TNM, BCLC, ALBI, PALBI, ALBI incorporated BCLC and ALBI-T scores.

**Results:** For 1910 patients, the mean age was 57 years, 1575 were males. At presentation, 50.6% were CTP A, 36.1% were CTP B and 13.4% were CTP C. Most of the patients were ALBI grade 2 (63.2%), 17.8% were ALBI grade 2A while 45.5% were ALBI grade 2B. ALBI grade 1 & 3 were 12% & 24.7% respectively. The overall median survival was 13 months; the median survival was ALBI grade 1 than ALBI 2 & 3 (28.8, 14 & 5 months respectively, p < 0.001). Moreover, the median survival for ALBI grade 2A patients was better than ALBI 2B (18.6 vs. 13 months respectively, p < 0.001). ALBI-T grades 0 & 1 patients had better median survival than those of ALBI-T grades 2, 3 & 4.2, 24.4, 17, 8, 9, 5 and 3 months respectively (p < 0.001). On adding the ALBI subclassification proposed by Osagusawa, the modified ALBI-T showed significant improvement in the median survival of modified ALBI-T grades 2, 3, 4, 5 and 6 to be 28.6, 20.9, 13.9, 8 and 4 months respectively. On comparing ALBI-T, CTP, TNM, ALBI, BCLC, ALBI (modified), PALBI, ALBI based BCLC and ALBI-T, it showed significantly better AUC (0.818 vs. 0.643, 0.620, 0.719, 0.734, 0.749 and 0.803, respectively).

**Conclusion:** Modified ALBI-T classifies patients with HCC more precisely than other scoring system.

**Introduction:** The debate on the matter of HCC recurrence risk and its aggressiveness in patients who have a history of previously and successfully treated HCC underd AAAs treatment is still open.

**Aims and Methods:** The present real-life multicenter, prospective study aims to evaluate the impact of new DAAAs therapies in HCV patients with a previous successfully treated HCC, in terms of neoplastic recurrence. From March 2015 to March 2017, 101 consecutive HCV patients with prior HCC underwent DAAAs treatment were enrolled. The assessment of neoplastic recurrence was used as primary outcome, while a secondary outcome was the evaluation of baseline characteristics predicting HCC recurrence.

**Results:** 83% of patients were in Child-Pugh class A, and 89% had a history of HCC. The median MELD of 9 and 69% in BCLC-B and 419 in BCLC-C stage. Median overall survival in the whole population was 33.9 months.

When different TACE procedures, irrespective of the BCLC stage, the ALBI grade and pALBI grade were significant predictors of overall survival (p = 0.001 and p < 0.0001 respectively), similar to the HAP and the mHAPII scores (p < 0.0001). When patients in different BCLC stages were considered, ALBI was a significant predictor of OS only in BCLC-C (p = 0.001) patients treated with TACE, pALBI was a significant predictor of OS in BCLC-B (p < 0.001) and BCLC-C (p < 0.01) similarly to HAP and mHAPII.

Similar data were obtained when only the first TACE procedure was considered in each patient (total of 901 patients, 460 BCLCA, 259 BCLC-B and 182 BCLC-C). Considering all BCLC stages, ALBI was a significant predictor of overall survival (p < 0.001) similar to the pALBI, HAP and mHAPII scores (p = 0.003). When different BCLC stages were considered, ALBI, pALBI and HAP were significant predictors of OS in BCLC-C (p = 0.008, p = 0.003 and 0.08 respectively), whereas mHAPII was not significant. PALBI was also a significant predictor of OS in BCLC-C (p = 0.005).

**Conclusion:** ALBI and pALBI offer additional simple and objective methods of assessing liver function in HCC and may be useful for selecting patients more likely to survive after TACE, especially ALBI in those belonging to the BCLC-C stage whereas pALBI in BCLC-B and BCLC-C stage.

**Introduction:** The prognosis of hepatocellular carcinoma is influenced by severity of liver function. Child-Pugh (CPS) and MELD scores have considerable limitations. Recently, the prognostic value of albumin-bilirubin (ALBI) [1] grade has been evaluated in patients undergoing HCC treatment with different modalities, but not specifically in patients undergoing TACE [2]. Moreover, the pALBI grade, which is included platelet count, is a surrogate marker ofportal hypertension [3].

**Aim:** To evaluate the role of ALBI grade and pALBI in predicting outcome for HCC patients who underwent transcatheter arterial chemembolization (TACE).

We retrospectively evaluated the prognostic significance of ALBI and pALBI in patients undergoing TACE recorded in the Istituto di Clinica, and compared it with other prognostic systems, including MELD, CPS, hepatoma arterial-embolization prognostic (HAP) and mHAPII.
**P0072** THE EFFECT OF DIRECT ACTING ANTIVIRALS ON THE OCCURRENCE AND RECURRENT OF HEPATOCELLULAR CARCINOMA: META-ANALYSIS OF 1438 PATIENTS

1Tanta University, Tropical Medicine Department, Tanta, Egypt
2Ain Shams University, Cairo, Egypt

**Contact E-Mail Address:** sherif_tropical@yahoo.com

**Introduction:** Prospective reports suggested an unexpected high rate of hepatocellular carcinoma (HCC) occurrence and recurrence following antiviral treatment using direct acting antiviral (DAA).

**Aims and Methods:** We aim to synthesize evidence about effect of DAA on the occurrence of HCC.

**Results:** Seven prospective cohort studies were included in the present review with a total of 1438 HCV patients. The pooled HCC occurrence rate in the DAA group was 2.7% (95% CI [0.015, 0.038]). The pooled HCC recurrence rate in the DAA group was 13.6% (95% CI [0.059, 0.214]); while the two-arms meta-analysis showed that the DAA group was associated with less risk of HCC recurrence compared to the control group (RR = 0.55, 95% CI [0.32, 0.96], p = 0.04). Pooled effect estimates did not differ significantly after subgrouping the patients according to DAA regimens. All pooled analyses were homogeneous.

**Conclusion:** The present meta-analysis showed that the rate of HCC occurrence or recurrence following DAA regimens is low.

**Disclosure:** Nothing to disclose

**P0073** PROGNOSTIC VALUE OF ALBUMIN BILIRUBIN SCORE AND ALBUMIN BILIRUBIN RATIO IN HEPATOCELLULAR CARCINOMA PATIENTS TREATED WITH TRANS-ARTERIAL CHEMOEMOBOLIZATION

H. Elalfy1, T. Besheer1, M. Abd El Maksoud2, M. Hassanny3, A. Mohammed El Nakib4

2Cairo University, Cairo, Egypt

**Contact E-Mail Address:** el_naqueeb@yahoo.com

**Introduction:** Albumin bilirubin score (ALBI) is a recently reported, simpler, more objective, and evidence-based alternative to the Child-Pugh (CP) score and Barat facility clinic liver cancer (BCLC) for prediction of survival and prognosis in hepatocellular carcinoma (HCC). Albumin bilirubin ratio is a novel method for detection of early recurrence of HCC after management.

**Aims and Methods:** This study aimed to validate prognostic value of both albumin bilirubin score and albumin bilirubin ratio in hepatocellular carcinoma patients treated with conventional transarterial chemomobilization (cTACE).

**Results:** The study enrolled 78 HCC patients with BCLC stage (A,B) underwent cTACE, all of them have complete response (CR) according to mRECIST criteria. ALBI score was measured before cTACE using this equation - 0.085 x (albumin g/l) + 0.66 x log (bilirubin μmol/l) and the ratio between albumin (g/l) and bilirubin (μmol/l) was mathematically calculated before TACE. Follow-up of the patients was done every 6 months for 36 months using dynamic imaging, liver, kidney functions and AFP.

**Results:** Early HCC recurrence (within the first 6 months) was observed in 28 patients, ALBI score was significantly associated with early tumor recurrence (p = 0.001). The Roc curve for ALBI score for detection of early recurrence of HCC after cTACE (at cut off value 0.637, sensitivity is 100% and specificity is 77%), for Albumin Bilirubin ratio (at cut off value 0.885, sensitivity is 95.2% and specificity is 71.4%). Both ALBI score and albumin bilirubin ratio were significantly positively correlated with Child Pugh score, BCLC staging and model for end stage liver disease (MELD) score (p = 0.001).

**Conclusion:** ALBI score and albumin bilirubin ratio could be used as prognostic indicators in HCC management and help in assessing early recurrence of HCC following TACE with high sensitivity and good specificity in comparison to other well-known scores like BCLC and Child -Pugh scores.

**Introduction:** Portal hypertension is determined both by ‘static’ fibrosis and ‘dynamic’ hemodynamic components. The correlation of fibrosis area and portal pressure has not been systematically assessed in different animal models and in human liver disease of different etiologies. This study hypothesized and tested the correlation of collagen-proportionate area (CPA) with portal pressure (PP) in animal models and with hepatic venous pressure gradient (HVPG) in patients with cirrhosis.

**Aims and Methods:** Carbon tetrachloride (CCl4) or bile duct ligation (BDL) models were used to mimic toxic or biliary cirrhosis in rats, respectively. Portal pressure was measured by direct cannulation of the portal vein. Patients underwent HVPG measurements and transjugular liver biopsy. Liver samples were stained by chrome-aniline-blue (CAB) or picro-sirus-red (PSR) and CPA was quantified by Imaged software.

**Results:** Portal pressure correlated with CPA both in BDL (R = 0.844, p < 0.001) and in CCl4 (R = 0.866, p < 0.001) animals. The ‘linear fitting’ curve was steeper in BDL than in CCl4 (PP = 2.303*CPA + 4.045) as compared to CCl4 (PP = 1.520*CPA + 4.794). Animals outside the 75% confidence interval of the expected PP (based on CPA) might have pronounced ‘dynamic’ components, e.g. in endothelial dysfunction, splanchic blood flow or portosystemic shunting. Similarly, in (n = 18) patients, HVPG correlated with CPA (R = 0.339, p = 0.17) yielding a ‘predicted’ HVPG (mmHg) of 0.663*CPA + 11.8. In patients with 25% higher HVPG as expected by the CPA-formula, we recorded higher vWF-Ag (368 ± 3 vs. 233 ± 50%, p = 0.048), IL6 (23 ± 8 vs. 8 ± 4 ng/l; p = ns), and bile acids (34 ± 18 vs. 7.3 ± 3 μmol/l; p = ns) than in patients with 25% lower HVPG as expected. More patients will be presented at congress.

**Conclusion:** CPA as the ‘static’ component of PHT correlates with PP/HVPG, with model-specific and etiology-dependent correlation estimates. Outliers to this curve imply profound alterations of ‘dynamic’ components of PHT, such as endothelial dysfunction, significant collateralization, bacterial translocation or a deranged gut-liver axis. Identification of outliers refines the assessment of vascular and hemodynamic dysfunction and may allow for personalized therapy of PHT.

P0075 PRONOSTIC FACTORS IN PATIENTS WITH PORTAL CAVERNOMA: RESULTS OF A PROSPECTIVE COHORT OF 131 CASES
Bologhine Hospital, Algiers, Algeria
Contact E-Mail Address: roougoum@yahoo.fr
Introduction: The portal cavernoma (PC) follows a chronic thrombotic occlusion of the portal vein and is often associated with toxic liver damage. It is remarkable that thrombosis of a portal branch causes portal hypertension, survival and causes of death and no data are available to identify those patients in which lifelong anticoagulation is necessary to prevent recurrent thrombosis.
Aims and Methods: The aim of the study was to analyze the long-term prognosis of patients with PC.
Results: The study was prospective and follow-up study of patients initially managed for portal cavernoma from January 2008 to June 2017. Patients with cirrhosis, cancer or hepatic cirrhosis syndrome were excluded. Portal hypertension was managed according to Baveno V recommendations. Anticoagulant therapy has been indicated according to current recommendations. All recurrent thrombosis, gastrointestinal bleeding, adverse events of anticoagulant therapy and death were registered.
Results: In this study 131 patients were included and followed up for a median time of 51.5 months. Of the 131 patients, 69 were men and 62 women, with a median age of 46.2 (23–81) years. PC was an incidental finding in 25 (19%) patients: 46 (35.2%) patients presented with abdominal pain; 60 (45.8%) patients presented with bleeding from portal hypertensive sources. Esophageal and/or gastric varices were present at diagnosis in 78 (59.5%) patients. Prothrombotic diagnosis was made in 72 (57.2%) patients. Among the factors identified, the most common were chronic myeloproliferative disease (CMD, 25.2%) and protein S deficiency (14.9%). 95 (72.5%) patients received long-term anticoagulation therapy. During the follow-up, 91 patients had no hemorrhagic or thrombotic events. The incidence rate of esophageal varices was 25%: 15 (11.4%) patients suffered from 23 episodes of gastrointestinal bleeding with no deaths. 6 patients had ascites and 15 patients had symptomatic cholangiopathy effectively treated with UDCA. New venous thrombotic episodes occurred in 11 (8.4%) patients of whom 6 were in the splanchic area. There was no case of occurrence or recurrence of intestinal infarction under anticoagulant therapy. 5 patients had latent CMD progression and 1 patient died of acute myeloid leukemia.
Conclusion: The long-term prognosis of patients with portal cavernoma is good, 70% of patients have a stable evolution. The combination of anticoagulants and the treatment of portal hypertension is effective in preventing thromboembolic recurrence and management of bleeding complications.
Disclosure: Nothing to disclose.

P0076 NGC STIMULATION AND PDE5 INHIBITION DECREASE SINUSOIDAL RESISTANCE AND REDUCE FIBROSIS IN RATS WITH BILIARY CIRRHOSIS

Introduction: Dysfunctional nitric oxide (NO) and cGMP signalling results in increased intrahepatic resistance in cirrhotic portal hypertension (PHT). PHT complications and major complications such as portal bleeding or ascites. Currently medical treatment of PHT is limited to non-selective beta-blockers, while there is no available treatment for liver fibrosis. We investigated the soluble guanylyl cyclase (sGC) stimulator riociguat (RIO) and activator cinaciguat (CIN) and phosphodiesterase-5 inhibitor tadalaftal (TADA) in bile duct ligated (BDL) rats.
Aims and Methods: Male Sprague-Dawley rats underwent BDL or sham-operation. Starting 1 week after surgery, RIO (0.5mg/kg), CINA (1mg/kg), TADA (1.5mg/kg) or vehicle (VH) were given orally (PP), mean arterial pressure, heart rate and splanchic/portal blood flow were measured. Liver fibrosis, hepatic inflammation and hepatic cGMP levels were assessed.
Results: Cirrhotic BDL-VEH rats showed significant increase in PP (13.07 ± 0.9mmHg) compared to healthy controls. In BDL animals RIO (9.96 ± 0.7mmHg, p = 0.021) and TADA (10.27 ± 0.8mmHg, p = 0.030) treatment decreased PP without affecting systemic hemodynamics. Intrahepatic vascular resistance decreased by RIO (2.86 ± 0.25, p = 0.45; 0.85 ± 0.4mmHg/mL, p = 0.005). Hepatic hydroxyproline content was reduced by RIO and TADA treatment (RIO: 350 ± 30μg/g, p = 0.003; TADA: 282 ± 50μg/g; p = 0.003 vs. BDL-VEH: 503 ± 20μg/g liver), whereas fibrotic tissue-unique-blue stained area decreased only by RIO (2.14 ± 0.3% vs. 4.15 ± 0.53%, p = 0.001). Both, RIO and TADA therapy decreased transaminases AST (RIO: ~36%, p < 0.001; TADA: ~24%, p = 0.006) and ALT (RIO: ~32%, p = 0.035; TADA: ~27%, p = 0.053). Limited BDL-VEH rats presented less hepatic hF expression (~56%, p = 0.053), indicating a reduction of neuroinflammation. Furthermore, hepatic GMP levels were significantly increased by RIO, but not by TADA or CINA. In cirrhotic BDL rats, 1mg/kg CINA caused weight loss, hypotension and increased lactate levels.
Conclusion: The sGC stimulator riociguat and the PDE5 inhibitor tadafalff showed beneficial effects in cirrhotic rats by reducing liver fibrosis and decreasing portal hypertension. High dosing of sGC activators such as 1mg/kg cinaciguat may be associated with toxic liver damage.

Introduction: The diagnosis of portal hypertension at a subclinical stage is important because of major prognostic and therapeutic consequences. In the latent stage, subclinical portal hypertension is not complicated with digestive hemorrhage and or Budd Chiari syndrome. The positive diagnosis of subclinical portal hypertension is confirmed according to current recommendations. All recurrent thrombosis, gastrointestinal bleeding, adverse events of anticoagulant therapy and death were registered.
Results: In this study 131 patients were included and followed up for a median time of 51.5 months. Of the 131 patients, 69 were men and 62 women, with a median age of 46.2 (23–81) years. PC was an incidental finding in 25 (19%) patients: 46 (35.2%) patients presented with abdominal pain; 60 (45.8%) patients presented with bleeding from portal hypertensive sources. Esophageal and/or gastric varices were present at diagnosis in 78 (59.5%) patients. Prothrombotic diagnosis was made in 72 (57.2%) patients. Among the factors identified, the most common were chronic myeloproliferative disease (CMD, 25.2%) and protein S deficiency (14.9%). 95 (72.5%) patients received long-term anticoagulation therapy. During the follow-up, 91 patients had no hemorrhagic or thrombotic events. The incidence rate of esophageal varices was 25%; 15 (11.4%) patients suffered from 23 episodes of gastrointestinal bleeding with no deaths. 6 patients had ascites and 15 patients had symptomatic cholangiopathy effectively treated with UDCA. P0079 LONG-TERM OUTCOME OF ENDOCOSMIC PAPILLARY LARGE-BALLOON DILATION FOR BILE DUCT STONES

Sendai City Medical Center, Department of Gastroenterology, Sendai, Japan

Contact E-Mail Address: murabayashi@openet.or.jp

Introduction: Endoscopic papillary large-balloon dilation (EPLBD) has been reported to be safe and effective for large, multiple common bile duct (CBD) stones. However, long-term outcome of EPLBD for such difficult stones has not been sufficiently determined.

Aims and Methods: The aims of this study was to evaluate long-term outcome of EPLBD for CBD stones. 102 consecutive patients who had undergone endoscopic CBD stone removal with EPLBD, which was defined as papillary dilation with a balloon having a diameter ≥ 12 mm between October 2011 and December 2021 were included in a prospective maintained database. Patients with previous history of surgical choledochoduodenostomy or endoscopic papillotomy, those with benign biliary stricture, and those in whom stones were not completely removed were excluded for evaluation of long-term outcome. Clinical or telephone surveys were conducted for patients who did not undergo periodical follow-up. Patients who rejected or inappropriately replied to the survey were also excluded. The main outcome measurement was the recurrence rate of CBD stones after complete stone removal with EPLBD during a follow-up. Risk factors for such recurrence were secondarily analyzed. In addition, other complications in the biliary system, such as acute cholecystitis and acute non-calculus cholangitis, and the patient survival period were analyzed.

Results: Complete stone removal with EPLBD was achieved in 99 patients (96.1%). After elimination according to the above-mentioned criteria, 93 patients were finally included in the retrospective analyses for long-term outcome. The mean age and the incidence of cerebrovascular accident were significantly higher in non-surgical group than surgical group (70.0% vs. 62.6%, p = 0.047) and surgical group (n = 37) vs. non-surgical group (n = 43) and surgical group (p = 0.026, respectively). No statistical difference for 44 patients, while 20 patients were still waiting for cholecystectomy 4 months after the acute episode. Readmission for biliary complications was observed in 24.1% of patients who didn’t undergo LC on the acute episode (second episodes of AC, cholangitis and biliary acute pancreatitis were reported), 3 of them required urgent surgery.

Conclusion: In the majority of patients with AC, surgical intervention was delayed due to the suspicion of concomitant cholecystolithiasis. However, in less than 40% of cases the diagnosis was confirmed and the requirement of endoscopic treatment was needed. This resulted in a readmission rate for biliary complications that was almost double compared to the non-surgical group. Admission Bilirubin cutoff found to be predictor of common biliary duct obstruction in this study was higher than established on ASGE guidelines. Considering that the appropriate management of this patients could be different according to these findings, more prospective studies should be formed.

Disclosure: Nothing to disclose

P0080 BILIRUBIN LEVEL AT ADMISSION AS PREDICTOR OF CONCOMITANT CHOLECYSTITIS AND RATE OF READMISSION FOR BILIARY COMPLICATIONS IN PATIENTS WITH DELAYED SURGERY FOR SUSPECTED BILIARY DUCT OBSTRUCTION

University Hospital Virgen Macarena, Gastroenterology Department, Seville, Spain

Contact E-Mail Address: carmenlaromerom@gmail.com

Introduction: Laparoscopic cholecystectomy (LC) is the gold standard treatment in acute cholecystitis (AC). Concomitant cholecystolithiasis incidence is 4–20%. However, the number of session was not different. Further large comparative studies are warranted.

Disclosure: Nothing to disclose
in recurrence rate between PTGBA and antibiotics only groups (7.7% vs. 11.8%) 2 patients underwent prophylactic cholecystectomy due to non-symptomatic period after non-surgical management.

Conclusion: Recurrence occurred in 9.3% of patients with AAC treated with non-surgical management and the treatment outcome of non-surgical group was not inferior to that of surgical group. Further studies are needed to clarify role of non-surgical management in patients with AAC.

Disclosure: Nothing to disclose

P0082 PREVALENCE OF FUNCTIONAL GASTRO-INTESTINAL DISEASES IN PATIENTS WITH UNCOMPLICATED CHOLECYSTOLITHIASIS; A SYSTEMATIC REVIEW AND META-ANALYSIS

Introduction: Cholecystolithiasis and functional gastrointestinal diseases (FGID) are both highly prevalent in the industrialised world. There are over 1.8 million ambulatory visits for symptomatic cholecystolithiasis in the United States. Incorrect assignment of abdominal symptoms may lead to inappropriate cholecystectomies with subsequent lack of benefit. We conducted a systematic review and meta-analysis to determine the prevalence of FGID in patients with uncomplicated cholecystolithiasis.

Aims and Methods: We searched MEDLINE, EMBASE and Web Of Science to identify studies reporting the prevalence of FGID in adults (≥18 years) with uncomplicated cholecystolithiasis. Pooled prevalences and 95% confidence interval (CI) were calculated. Subgroup analyses were performed according to diagnostic criteria used and for dyspepsia and irritable bowel syndrome (IBS) separately.

Results: Of the 1,696 studies evaluated, 11 reported the prevalence of dyspepsia and IBS in a total of 5,089 cholecystolithiasis patients. The pooled prevalence of FGID was 66.8% (95% CI 40% - 89%); 72.7% (95% CI 56% - 87%) for dyspepsia and 42.5% (95% CI 3% - 91%) for IBS. There were no statistically significant differences between diagnostic criteria.

Conclusion: This study finds that 67% of patients with cholecystolithiasis have FGID. In the United States this comprises 1.2 million patients. This is a concern, as these patients are at risk of cholecystectomy that will not benefit them. Extra measures to exclude FGID as a cause of abdominal symptoms, prior to cholecystectomy, is warranted.

Disclosure: Nothing to disclose

P0085 PRACTICE PATTERNS FOR THE MANAGEMENT OF CONCOMITANT GALLSTONES AND CHOLEDOCHOLITHIASIS

Y. Abdilla, J. Gerada
Mater Dei Hospital, Mdina, Malta

Contact E-Mail Address: jugeren.gerada@gov.mt

Introduction: Patients with concomitant gallstones and common bile duct (CBD) stones should have endoscopic retrograde cholangiopancreatography (ERCP) followed by cholecystectomy.

Aims and Methods: We studied the success rate of ERCP, and recurrent cholecdocholithiasis in those who did and did not have cholecystectomy post-ERCP. All patients, diagnosed with CBD stones on imaging between September 2015 and July 2017, and had subsequent ERCP + sphincterotomy, were retrospectively included in this study. Data was collected from medical notes.

Results: 126 patients underwent ERCP for stone extraction. CBD was cannulated in 94%, 20% had normal ERCP. 92 patients (80%) had CBD stones at ERCP. 58 (63%) had complete stone extraction with 1 ERCP (76%), 2 ERCPs (19%), >2 ERCPs (5%). 19 (21%) were lost to follow-up or deemed unfit for repeat ERCPs. 13 (14%) were still undergoing regular ERCPs. 2 (2%) had surgical CBD exploration.

Conclusion: Only 41% (29/71) underwent cholecystectomy post-ERCP. 93% (27/29) remained CBD stone-free at a mean follow-up of 1 year (5 - 23 months). In the 59% (42/71) who did not have cholecystectomy post-ERCP, 95% (40/42) remained CBD stone-free at a mean follow-up of 1 year (1 - 24 months). 5% developed new CBD stones requiring another ERCP. Cholecystectomy post-ERCP was not performed in 60%.

Discussion: Patients with cholecdocholithiasis-free survival was comparable at 1 year in patients who did and did not have a cholecystectomy post-ERCP. This suggests strong benefits from sphincterotomy alone, however cholecystectomy would still be necessary to prevent cholecystitis, biliary colic, cholangitis or biliary pancreatitis.

P0086 PREVALENCE AND RISK FACTORS OF CHOLELITHIASIS IN CROHN’S DISEASE

University Hospital Bratislava and Faculty of Medicine Comenius University in Bratislava, 5th Department of Internal Medicine, Sub dept. of Gastroenterology & Hepatology, Bratislava, Slovakia

Contact E-Mail Address:igor.sturdi@gmail.com

Introduction: Cholelithiasis occurs in patients with Crohn’s disease more frequently than in a healthy population. The cause of this difference has not been satisfactorily explained, nor its risk factors.

Aims and Methods: The aim of our study was to determine the prevalence of cholelithiasis in CD patients, to compare prevalence with a control group and to analyze the risk factors of cholelithiasis. We performed a monocentric retrospective case-control study. The cohort consisted of all CD patients who underwent abdominal ultrasound from January 2007 to January 2018 at the IH Center of the 5th Department of Internal Medicine in Bratislava. The control group consisted of 505 patients, who underwent ultrasound at the same department because of dyspepsia and were age and gender matched. Medical records were reviewed and patients demographics, behavior, localisation, duration and number of flare of CD, number and type of bowel resections, number and length of total hospitalization, number of total parenteral nutrition treatments and presence of cholelithiasis and its characterization were noted. An univariate and a multivariate analysis were performed using logistic regression analysis (with cholelithiasis as the dependent variable). Prevalence and odds ratios were calculated with their 95% confidence intervals.

Results: The study cohort consisted of 238 CD patients and 238 controls. The prevalence of cholelithiasis in CD group was 12.6% and 9.2% in control group (RR 1.36, p=0.24). In the univariate analysis, we observed cholelithiasis association with multiple risk factors such as - age, age at CD diagnosis, inflammatory versus aggressive disease behaviour, duration of disease, abdominal resection, number of intestinal resections, length of ileal resection, number of corticosteroid treatments, hospitalizations and total parenteral nutrition treatments. The age (OR 1.077, 95% CI 1.043–1.112, p < 0.001) and the number of total parenteral nutrition treatments (OR 1.812, 95% CI 1.131–2.903, p = 0.013) were determined as independent risk factors for cholelithiasis in CD patients by multivariate analysis.

Conclusion: The prevalence of cholelithiasis in our CD patient population was significantly higher than in the control group. We identified the age of patient and the number of parenteral nutrients as the independent risk factors of cholelithiasis in CD patients.

Contact E-Mail Address: marcus.hollenbach@web.de

Introduction: Nuclear Protein 1, Transcriptional Regulator gene (NUPR1, p8) was first described as an overexpressed gene in pancreatic carcinomas and encodes a ubiquitous nuclear and cytoplasmic stress protein. Analysis of insulin sensitivity and glucose tolerance in p8 haplodeficiency and p8-knockout mice revealed counterintuitive results. Thus, we analyzed glycemic control of p8 in mice fed with standard (SD) and high-fat diet (HFD).

Aims and Methods: p8+/− mice and wild type (p8+/+) littermates were used to study glucose homeostasis. We determined glucose (immunohistochemistry) and insulin levels (ELISA) from isolated pancreatic islets and analyzed beta cell mass. In addition, hyperinsulinemic- euglycemic glucose clamp technique, i.p. glucose tolerance test (ipGTT), i.p. insulin tolerance test (ipITT) and metabolic chamber analysis over 72 hours were performed in SD (4% fat) and HFD (55% fat) groups.

Results: p8+/− mice showed no differences in glucose content but higher levels of insulin in pancreatic islets upon glucose stimulation compared to wildtype littermates. p8 deficiency resulted in elevated beta cell mass but was not associated with increased insulin resistance in ipGTT in both SD and HFD groups. Glucose clamp tests also revealed no evidence of association of p8 deficiency with insulin resistance. Metabolic chamber analysis showed equal energy expenditure in p8+/− mice and wildtype animals.

Conclusion: Complete p8 depletion may contribute to glucose metabolism by means of stress-induced insulin production and beta cell mass. Nevertheless, p8 knockout showed no impact on insulin resistance in SD and HFD fed mice.

Introduction: Obestatin, a 23-amino acid peptide encoded by the ghrelin gene, and the GPR39 receptor were reported to be involved in the control of mitogenicity of gastric cancer cells. Our data strongly suggest the involvement of the obestatin/GPR39 system in the pathogenesis and/or clinical outcome of human gastric cancer in which in addition, GPR39 expression was shown to be closely related to proliferation and poor prognosis.

Conclusion: Disclosure: Nothing to disclose

Introduction: There is evidence that the mature adult pancreas has the ability to regenerate, similar to the liver, although to a lesser extent. Studies in animal models confirmed the plasticity and regeneration of both exocrine and endocrine pancreatic cells. Pancreatic stellate cells (PSC) play a major role in pancreas regeneration after partial pancreatectomy. Obestatin, a peptide derived from preproghrelin, and its receptor GPR39 have been described in the endocrine pancreas. Recent studies showed that the expression of GPR39 in the stellate cells is increased in the area of ischemia.Receptor expression in rat pancreas undergoing ischemia injury is increased.

Conclusion: Disclosure: Based on the previous background, the main objective of the present study was to evaluate the regulatory function of the obestatin/GPR39 system in the human pancreatic stellate cells (RLT-PSC).

Disclosure: Nothing to disclose

Introduction: The uptake of 11C]-methionine ([11C]MET) is associated with pancreatic endocrine and exocrine activity such as insulinogenic index and pancreatic digestive enzyme release. However, studies that examine both, the impact of endocrine and exocrine function, on methionine uptake of the pancreas are rare. Cholecystokinin (CCK), a trigger of pancreas secretion is altered after operations that accelerate gastric emptying, such as gastroectomy. Similarly insulin release is modified due to elevated glucose plasma concentrations and via GLP-1. The purpose of this study was to shed light on the relationship between the secretion of CCK, insulin release and [11C]MET uptake in subjects having undergone partial pancreateicoduodenectomy (PD).

Disclosure: Nothing to disclose
Aims and Methods: 19 tumor-free survivors after PD (age mean ± SD: 61 ± 8.7 yr; 13 males) were given a mixed meal, and pancreatic CCK, insulin and glucose concentrations were measured before and at 10, 20, 30 and 60 minutes after ingestion. Simultaneously 800 MBq of [11C]MET were administered and the activity (maximum tissue standardized uptake values [SUVmax]) over the pancreas was measured using PET-CT at 15, 30 and 60 minutes after injection. Beta cell function was calculated from basal plasma glucose and insulin concentrations. Area under the curve [AUC] was calculated for insulin, CCK and SUVmax (methionine uptake).

Results: CCK AUC0-60 (R2 = 0.26, p = 0.05), beta cell function (R2 = 0.54, p < 0.01) and insulin AUC0-60 (R2 = 0.66, p < 0.01) correlated with the SUVmax AUC0-60. Multivariate analysis revealed CCK, basal beta cell function and post-prandial insulin (AUC0a) concentrations as significant independent predictors of [11C]methionine uptake (R2 = 0.64, p < 0.01, Table 1, Figure 1).

Table 1. Multiple linear regression on the dependent variable ‘methionine SUVmax AUC0-60′ in patients after PD (R2 = 0.84, p < 0.01).

Conclusion: The association between CCK secretion, beta cell function and post-prandial insulin release with pancreatic [11C]MET uptake might suggest the representation of digestive enzyme and insulin metabolism. Further studies are needed to evaluate the relative impact of exocrine and endocrine pancreatic function on the uptake of this tracer.

PO092 CLINICAL STUDY OF IMPROVEMENTS IN PANCREATIC BLOOD FLOW AS MEASURED BY PERFUSION TOMOGRAPHY IN PATIENTS WITH SEVERE ACUTE PANCREATITIS AND ADMINISTERED RECOMBINANT HUMAN SOLUBLE THROMBOMODULIN

T. Eguchi1, Y. Tsuchi, M. Tsujimae1, A. Kanamori1, K. Matsumoto1, S. Goðíðason2, N. Gede6, V. Sallinen7, M. Macarie8, I. Torok8, C. Gog9, Zs. Gyoðmer1, A. Vincze2, F. Izbeki3, J. Hamvas4, M.M. Hajdune Dr. Varga5, Y. Tsuji2, M. Tsujimae1, A. Kanamori1, K. Matsumoto1, T. Eguchi T, et al., Department of Internal Medicine II, Munich, Germany

Introduction: Pancreatic circulation failure due to disseminated intravascular coagulation (DIC) is a significant factor in determining the severity of pancreatitis. Pancreatic circulation failure affects walled-off necrosis (WON) caused by severe acute pancreatic necrosis. A study has shown that patients with severe acute pancreatitis (SAP) administered recombinant human soluble thrombomodulin (rTM) exhibit significant improvements in coagulation anomalies and inhibited sepsis development [1]. Peripheral blood perfusion imaging (PCT) in advanced imaging technique for evaluating blood circulation in SAP, can accurately diagnose the development of pancreatic necrosis in the early stages of SAP. PCT can also be used to predict the severity of acute pancreatitis [2].

Aims and Methods: This study applies PCT to investigate whether rTM improved pancreatic blood flow (PBF) in cases of SAP involving pancreatic necrosis.

We retrospectively analyzed 27 SAP patients with pancreatic necrosis treated from January 2015 to January 2018 at Osaka Saiseikai Nakatsu Hospital. All patient data was gathered from an electronic database. The 27 SAP patients were divided into two groups: SAP patients with DIC treated with rTM (380 U/kg for 30 minutes, once daily: the rhTM(DIC(-)) group) and patients without and did not get treated with rTM (DIC(+)) group, 13 patients. To determine a diagnosis of pancreatic necrosis, we measured PBF with PCT within 48 hours and set a criterion of 25% or greater reduction of PBF in a region of 1 cm² or more compared to normal pancreatic parenchyma. We assessed the extent of pancreatic necrosis based on the ratio of ischemic pancreatic PBF/nor mal pancreatic PBF. We calculated the PBF ratio, APACHE II SOFA, JPN prognostic factor (by the Japanese severity scoring system), and JAAM DIC scores within 48 hours of hospitalization and again on the seventh day of hospitalization (day 7).

Results: The background data for the subjects is as follows: mean age 62.6 years; male/female ratio: 18:9; cause: 11 alcohol, 5 gallstone, 6 idiopathic, 3 cases of EIRC, 2 other, and 1 fatality. In the Revised Atlanta Criteria, the rTM(DIC(-)) group was significantly severer: the rTM+(DIC(+)) group vs. DIC(-) group (7 severe; 6 moderate vs. 1 severe; 9 moderate). We found no differences in SOFA scores between the two groups as of the time of hospitalization (i.e., rTM+(DIC(+)) vs. DIC(-)): 3.8 ± 2.1 vs. 2.8 ± 2.4. However, we found significant differences with respect to the prognostic factor (3.5 ± 1.6 vs. 1.8 ± 1.3), mean APACHE II scores (12.5 ± 5.8 vs. 8.2 ± 4.1), and JAAM DIC scores (3.7 ± 1.5 vs. 1.9 ± 1.3) (p < 0.05). PBF ratios within 48 hours of hospitalization did not differ between the rTM+(DIC(+)) and DIC(-) groups: 0.560 ± 0.144 vs. 0.673 ± 0.241. The PBF ratio for rTM+(DIC(+)) group was significantly higher (0.760 ± 0.218) on day 7 (p < 0.01). The PBF ratio for the DIC(-) group without rTM treatment failed to improve (0.670 ± 0.119) on day 7. The PBF ratio for the rTM+(DIC(+)) group on day 7 was significantly higher than for the DIC(-) group (0.760 ± 0.218 vs. 0.670 ± 0.119) (p < 0.05). WON occurred in 12 cases (44.4%).

Conclusion: Since pancreatic ischemia is defined as a reduction in PBF of 25% or more, we considered ischemia in many of the patients meeting this criteria was significant, although the syndrome of the rTM+(DIC(+)) group had significantly worse, improvements in the PBF ratio were significantly better. Since rTM improved coagulation anomalies, we considered it may improve PBF and that rTM offers a new therapeutic option in treating pancreatic ischemia.

Disclosure: Nothing to disclose.

Aim of the Study: The purpose of the study is to evaluate the efficacy of an innovative combination of medications, compared to the conventional treatment, in the management of acute pancreatitis.

Methods: A randomized controlled trial was conducted in patients diagnosed with acute pancreatitis at the Department of Gastroenterology, University of Debrecen, Hungary.

Results: The results showed a significant decrease in the duration of hospitalization and the severity of the disease in the group treated with the innovative combination, compared to the control group.

Conclusion: The innovative combination of medications offers a promising approach in the treatment of acute pancreatitis.

Disclosure: Nothing to disclose.

Introduction: Both alcohol consumption and cigarette smoking have been recognized as risk factors on the pancreas. These adiposity effects are very close together, so careful investigations are crucially needed to understand their independent/synergic effects on the pancreas.

Aims and Methods: To examine the clinical effects of alcohol consumption and/or smoking in patients with acute pancreatitis (AP).

A total of 1435 adult patient were enrolled from 2012 to 2017 with the diagnosis of AP in 28 healthcare centres by the Hungarian Pancreatic Study Group. Specific questionnaires for AP including information on cigarette smoking and alcohol consumption were used, whereas detailed clinical data such as the results of laboratory parameters and imaging, the course and the outcome of AP episodes were collected.

Results: 692 (48.32%) of the patients were non-drinkers and non-smokers (ND-N), 615 of the patients were drinkers (D) (43.0%), 279 (45.4%) of the drinkers did not smoke (D-NS), whereas 336 (54.6%) of them were smokers (D-S) as well. The age of onset was 61.1y in the ND-NS group, 55.1y in the D-NS and 46.3y in the D-S group. The female/male ratio was 0.6 in the ND-NS group, 3.15 in the D-NS and 1.4 in the D-S group. Smoking alone had an effect on the BMI (ND-NS: 28.2, D-NS: 28.2), but smoking in addition to drinking decreased it (D-S: 25.7). Concerning the parameters on admission the ND-NS, D-NS and D-S groups were as follows: amylase (U/L): 1310 ± 1351, 1609 ± 1194, 737 ± 1237; lipase (U/L): 3233 ± 4911, 2617 ± 3350, 2035 ± 6617; CRP (mg/L): 53 ± 77, 51 ± 72, 63 ± 80; WBC (G/L): 13 ± 5.5, 13.3 ± 6.4, 13.6 ± 5.7. Smoking had synergic effect with drinking on local complications (ND-NS: 34.4%, D-NS: 37.5%, D-S: 44.1%) such as necrosis (8.8%, 11.0%, 15.6%), development of pseudocyst (0.9%, 9.2%, 13.3%) and fluid collection (28.3%, 31.3%, 35.5%). The percentage of moderate AP copied the same pattern (24.9%, 26.8% and 31.9%). We could see no difference in mortality and the rate of severe AP. Deaths were higher among the other 2 groups. Of the abdominal adiposity phenotypes we also elevate the risk for acute recurrent pancreatitis (ARP). 18.9% of the patients had ARP in the ND-NS, 23.5% in the D-NS, whereas 31.9% in the D-S groups.

Conclusion: Drinking and smoking together result in the onset of pancreatitis 15 years earlier. It elevates the risk for recurrence of the disease. Drinking and smoking synergize with each other and increase the rate of local complications.

Introduction: Acute pancreatitis (AP) is a sudden inflammation of the pancreas. The early evaluation and accurate prediction of AP severity is vital, as severe AP can result in multiple organ failure (POF) and mortality.

Aims and Methods: This study is to explore the predictive significance of visceral adiposity (VFV) and visceral adiposity index (VAI) on AP severity, which may go together, therefore careful investigations are crucially needed to understand the differences in abdominal adiposity and ectopic fat phenotypes and pancreatitis-related factors (aetiology, severity) in individuals after AP have never been studied.

Aims and Methods: The aim is to investigate phenotypic differences in distribution of abdominal adipose tissue and ectopic fat between individuals after AP (with and without diabetes) using magnetic resonance imaging (MRI). The secondary aim was to determine pancreatitis-related factors associated with abdominal adiposity and ectopic fat phenotypes. A total of 156 patients had been diagnosed prospectively with AP were included in this study. They were recruited after an average time of 28 months after last episode of AP.

Results: Of the abdominal adiposity phenotypes, VFV was significantly higher in the diabetes (2715.3 ± 1077.6 cm3) as compared with no diabetes (1982.3 ± 1092.4 cm3) and healthy (1162.6 ± 740.4 cm3) groups (p < 0.001). Moreover, V/S ratio was significantly higher in the diabetes (0.97 ± 0.27) as compared with no diabetes (0.68 ± 0.42) and healthy (0.52 ± 0.34) groups (p < 0.001). Of the ectopic fat phenotypes, PF% was significantly higher in the diabetes (10.2 ± 1.2%) as compared with no diabetes (9.2 ± 1.7 %) and healthy (7.9 ± 1.9 %) groups (p < 0.001). Other studied phenotypes did not differ significantly between the groups. C-reactive protein levels during hospitalization for AP were associated with significantly increased VFV in unadjusted (β = 3.32; 95% CI, 1.68, 4.96; p < 0.001) and adjusted (β = 2.71; 95% CI, 1.24, 4.19; p < 0.001) models. Biliary aetiology of AP was associated with a significantly increased PF% in adjusted model (β = 0.67; 95% CI, 0.01, 1.33; p = 0.047).

Conclusion: The findings of this study show, for the first time, that individuals after an episode of AP have abnormal adiposity phenotypes, particularly increased visceral fat and pancreatic fat depots. Further, these depots are significantly associated with the presence of diabetes after AP. Levels of C-reactive protein during hospitalisation for AP are significantly associated with VFV whereas biliary aetiology of AP is significantly associated with PF%.

Introduction: Lipolysis of adipocyte triglycerides by pancreatic lipases results in the release of free Fatty Acids (FA) seem to be an important factor in the release of low-density lipoprotein (LDL-C) and triglycerides (TG) on the development of atherosclerosis. We aimed to investigate if differences in dietary fat patterns are associated to different composition of fat storages, and thus to a different frequency of complications and death in AP.

Aims and Methods: Our aim was to investigate whether different patterns of fat intake are associated to worse outcomes in AP. We used data from the Atlantis project, a 23-center prospective nation-wide Spanish database aiming to investigate the determinants of morbidity and mortality in acute pancreatitis. Dietary fat intake (fat intake, proportion of fats, SFAs, mono and polyunsaturated fats) from different regions of Spain were retrieved from the ANIBES (Anthropometry, Intake and Energy Balance in Spain) cross-sectional study using a nationally representative sample of the Spanish population. Outcome variables included: necrotizing pancreatitis (pancreatic gangrene, pancreatic fat necrosis), persistent organ failure (POF) and mortality. Variables addressing dietary fat intake were divided according to their median value into low and high intake. Univariate (Chi-square) and multivariate (binary logistic regression) analysis were performed. The variables included on the multivariate analysis model were: Charlson comorbidity index ≥ 3 (includes also age), alcohol etiology, gender, obesity and recurrent AP; adjusted Odds Ratio (aOR) were calculated.

Results: 1,653 episodes of AP were analyzed. Etiology was biliary in 28.3%, 54% of the patients were male, AP was associated to necrosis in 17%, to persistent organ failure (POF) in 7% and mortality was 4%. On univariate and multivariate

A163

United European Gastroenterology Journal 6(8S)
analysis, a high SFA intake was independently associated to a lower risk of necrosis [15 vs. 19%, aOR 0.746 (0.570–0.978), p = 0.034], a lower risk of POF [5 vs. 9%, aOR 0.550 (0.367–0.822), p = 0.004] and mortality [3 vs. 6%, aOR 0.548 (0.329–0.914), p = 0.021].

Conclusion: Our study suggests that a high saturated fatty acid intake is associated to improved outcomes in acute pancreatitis, resulting in a 50% lower risk of persistent organ failure and mortality.

Introduction: During the past decades, obesity rates have increased sharply. As there is a growing number of cases in which acute pancreatitis (AP) is accompanied by obesity, we found it clinically relevant to investigate how body-mass index (BMI) affects the outcome of the disease.

Aims and Methods: Our aim was to quantify the association between subgroups of BMI and the severity and mortality of AP. A meta-analysis was performed using the Preferred Reporting Items for Systematic Review and Meta-analysis Protocols. 3 databases (PubMed, EMBASE and Cochrane Library) were searched for articles containing data on BMI, disease severity and mortality rate of AP. English-language studies from inclusion to 19 June 2017 were checked against our predetermined eligibility criteria. The included articles reported all AP cases with no restriction on the etiology of the disease. In severity analyses we only involved studies that classified AP cases according to the Atlanta Criteria. Odds ratios (OR) and mean differences (MD) were pooled using the random effects model by the DerSimonian-Laird estimation and displayed on forest plots. The meta-analysis was registered in PROSPERO under number: CRD42017077890.

Results: Altogether 19 articles were included in our meta-analysis, containing data on 9,997 patients. Severity: The subgroup analysis shows a direct association between AP severity and BMI. BMI > 25 compared to normal BMI and BMI 25–30 subgroups. A BMI > 30 results in a 3 times higher risk of persistent organ failure and mortality compared to the non-severe group (MD 5 vs. 9%, aOR 0.548 (0.329–0.914), p = 0.021).

Adipose tissue specific adipokines, omentin and vaspin, hold promise for future clinical investigation of tissue-specific IR.

**P0098 GENERAL AND ADIPOSE TISSUE-SPECIFIC INSULIN RESISTANCE AFTER AN EPISODE OF ACUTE Pancreatitis**

R. Singh, S. Pendharkar, A. Cervantes, J. Cho, V. Mitunda-Soberanis, M. Petrov

The University of Auckland, Auckland, New Zealand

Contact E-Mail Address: ruma.singh@auckland.ac.nz

Introduction: Emerging evidence indicates that individuals after an episode of acute pancreatitis (AP) are at an increased risk of developing metabolic derangements, in particular new-onset prediabetes or diabetes after AP.1 The link between general obesity and insulin resistance (IR) was established decades ago, however the impact of body fat distribution on IR has gained attention only recently and is not completely understood. In the setting of AP, the association between abdominal obesity and IR, and a comprehensive assessment of various IR indices in post-pancreatitis setting, is lacking.

Aims and Methods: The aim of this study was to investigate associations between abdominal obesity and IR (general and adipose tissue-specific) in patients with AP independent of the effect of covariates including diabetes mellitus, and to determine the relative accuracy of several indices of IR in characterising abdominal obesity. Patients were eligible for this cross-sectional study if they were previously admitted with a primary diagnosis of AP, established prospectively. Fasting venous bloods were collected to measure glucose, insulin, free fatty acids, glycerol, adiponectin (AD), omentin (OM), and vaspin(VAS). The IR indices - homeostasis model assessment of IR (HOMA-IR), adipose tissue IR (Adipo-IR), insulin*glycerol (IG) index, HOMA-AD, HOMA-OM, and HOMA-VAS were calculated. Abdominal obesity was defined according to the National Cholesterol Education Program Adult Treatment Panel III (ATP III) guidelines.2 Modified Poisson regression was conducted, with statistical model adjusting for patient-, metabolic-, and pancreatitis-related risk factors. Areas under the receiver operating characteristic (ROC) curves were calculated to determine the relative accuracy of the studied indices followed by determination of agreement between the two new indices (HOMA-OM, HOMA-VAS) and HOMA-IR.

Results: Of the 92 individuals recruited, 41 had abdominal obesity. The median (interquartile range) time since AP was 24 (7-46.5) months. Insulin resistance indices HOMA-IR, IG index, HOMA-OM, and HOMA-VAS were significantly associated with abdominal obesity, both in unadjusted and adjusted models (Table 1). Area under ROC curves for HOMA-IR was 0.698 (95% CI, 0.591, 0.791; p < 0.001), for IG index was 0.695 (95% CI, 0.585, 0.791; p < 0.001), for HOMA-OM was 0.756 (95% CI, 0.648, 0.845; p < 0.001), and for HOMA-VAS was 0.735 (95% CI, 0.625, 0.827; p < 0.001). There was a good agreement between observed HOMA-IR values and values obtained from HOMA-OM (p = 0.733) and HOMA-VAS (p = 0.595).

Conclusion: Individuals with abdominal obesity after AP have a significantly higher IR, independent of diabetes and other covariates. Visceral adipose tissue specific adipokines, omentin and vaspin, hold promise for future clinical investigation of tissue-specific IR.

inhibit Hpa activity both
Contact E-Mail Address:далът126@gmail.com

Introduction: pancreatic (AP) is one of the most common diseases in gastroenterology. However, neither the etiology nor the pathophysiology of the disease is fully understood and no specific or effective treatment has been developed. We previously showed that heparase (Hpsa) appears to play an important role in the pathogenesis of AP and that Hpsa inhibitors significantly reduced the severity of the AP in an animal model. Aspirin has also been demonstrated to inhibit Hpa activity both in vitro and in vivo. We hypothesize that combination of Aspirin and aspirin can ameliorate AP more efficiently than each drug alone.

Aims and Methods: The current study examines whether combination of Aspirin with PG545 or Roneparstat (SST0001), 2 inhibitors of Hpsa, exerts superior pancreateo-protective effect in cerulein-induced AP in mice, vs each compound alone.

Heparase-overexpressing transgenic mice (Hpsa-TG) and wild-type (WT) BALB/c mice (n = 7–8) were intraperitoneally injected with either cerulein (50 mg/kg; 5 times, at 1 hour apart) or vehicle, with or without either PG545 (0.4 mg/kg, kind gift of Dr. Edward Hammond, Zucero Therapeutics, Brisbane, Queensland, Australia), Roneparstat (2 mg/mouse, kind gift of Dr. Alessandro Noseda, Leadiant Biosciences S.A., Mendrisio, Switzerland), Aspirin (250 mg/kg, kind gift of Dr. Harald Noseda, Leadiant Biosciences S.A.). The animals were sacrificed 24 hours following the induction of pancreateitis. The severity of AP and architectural structure changes were evaluated by serum pancreatic enzyme (amylase and lipase) levels, inflammatory markers, histological examination (determined by organ-specific characteristics). The costs of care were 25% less in group A.

Disclosure: Nothing to disclose

P0101 CENTRALIZED CARE OF ACUTE PANCREATITIS SIGNIFICANTLY IMPROVES ITS OUTCOMES

S. Go´ di1,2, U. Bhattacharya2, S. Kinaneh2, N. Ilan2, P. Steen2,2, D. Ben Hemo2

Conclusion: Administration of either Aspirin or Hpa inhibitor exerts protective effects against Cerulein-induced AP. Interestingly, combination of Aspirin and Hpa inhibitors completely abolished AP, providing a rational basis for the treatment of this clinical setting.

Disclosure: Nothing to disclose

P0099 COMBINATION OF HEPARASE INHIBITORS AND ASPIRIN DYNAMICALLY AMELIORATES ACUTE PANCREATITIS IN AN ANIMAL MODEL

Aims and Methods: The current study examines whether combination of Aspirin with PG545 or Roneparstat (SST0001), 2 inhibitors of Hpsa, exerts superior pancreateo-protective effect in cerulein-induced AP in mice, vs each compound alone. Results: Results: 195 patients in the specialized center (group A) and 160 patients in the general medical hospital (group B). There was no difference in the mean age (57.02, ±71.6 vs. 57.31, ±16.50, p = 0.872) and sex ratio (56% males vs. 57% males, p = 0.837) between group A and B; allowing comparison without selection bias. Gender differences (42.0% vs. 51.7%, p = 0.13) were also observed in group A and that Hpsa inhibitors significantly reduced the severity of the AP in an animal model. Aspirin has also been demonstrated to inhibit Hpa activity both in vitro and in vivo. We hypothesize that combination of Aspirin and aspirin can ameliorate AP more efficiently than each drug alone.

Aims and Methods: The current study examines whether combination of Aspirin with PG545 or Roneparstat (SST0001), 2 inhibitors of Hpsa, exerts superior pancreateo-protective effect in cerulein-induced AP in mice, vs each compound alone.

Heparase-overexpressing transgenic mice (Hpsa-TG) and wild-type (WT) BALB/c mice (n = 7–8) were intraperitoneally injected with either cerulein (50 mg/kg; 5 times, at 1 hour apart) or vehicle, with or without either PG545 (0.4 mg/kg, kind gift of Dr. Edward Hammond, Zucero Therapeutics, Brisbane, Queensland, Australia), Roneparstat (2 mg/mouse, kind gift of Dr. Alessandro Noseda, Leadiant Biosciences S.A., Mendrisio, Switzerland), Aspirin (250 mg/kg, kind gift of Dr. Harald Noseda, Leadiant Biosciences S.A.). P0013 DIAGNOSIS, TREATMENT AND LONG-TERM OUTCOMES OF AUTOIMMUNE PANCREATITIS

Conclusion: Our data suggests that treatment of AP in specialized centers improves its mortality, the quality of care, the length of hospitalization and reduces the costs of care.

Disclosure: Nothing to disclose

P0102 GENESTIN INHIBITS THE ACTIVATION OF PANCREATIC STELLATE CELLS BY PI3K/akt/mTOR SIGNALING PATHWAY

R. Xue1, J. Hao2
Beijing Chao-yang Hospital, Capital Medical University, Department of Gastroenterology, Beijing, China

Conclusion: Administration of either Aspirin or Hpa inhibitor exerts protective effects against Cerulein-induced AP. Interestingly, combination of Aspirin and Hpa inhibitors completely abolished AP, providing a rational basis for the treatment of this clinical setting.

Disclosure: Nothing to disclose
Aims and Methods: We aimed to determine clinical presentation together with biochemical features of AIP in Japan. This was a single-center, retrospective, cohort study of patients with histologically confirmed or highly probable diagnosis of AIP according to ICDC criteria. Clinical/radiological characteristics, type of treatment and its outcomes were collected and was used for statistical analysis.

Results: 71 patients with AIP (87.3% with type 1), were evaluated at Karolinska University Hospital between 2004 and 2018; 49.2% males, mean age 49.2 years (range 44.7–53.8). Among them, 28.1% were histologically confirmed, 35.2% presented with jaundice, 22.5% with acute pancreatitis, 19.4% had non-specific symptoms such as weight loss or abdominal pain, 40.8% displayed other organ involvement (OOL). Radiologically, 40.5% displayed a focal mass, 36.2% a focal pancreatic enlargement, 27.5% a sausage-like pattern, 27.5% signs of acute pancreatitis, 10.1% had multiple pancreaticat. In total 58 patients (81.6%) underwent treatment comprising different medications: 46 (79%) cortisone, 7 (12.0%) atazanavir, 5 (8.6%) other immunosuppressives drugs. 26 (36.6%) underwent biliary stenting and 12 (16.9%) surgery due to suspicion for pancreatic malignancy. All (100%) of patients treated with cortisone, displayed a clinical response. After a mean follow-up of 46.7 months, 97.1% of patients were alive, 70% displayed a radiological complete response, 89.6% were treatment-free. None developed pancreas cancer but 1 patient (1.4%) developed mucinous cystic neoplasm (MCN) with high-grade dysplasia and was therefore successfully operated. 59.3% of patients developed pancreatic exocrine insufficiency (PEI) of which 76.4% had a severe form (fetal elastase-1 < 0.01 μg/g) and 23.6% of patients developed diabetes mellitus (pancreatic endocrine insufficiency) of which 73.3% requiring insulin.

Conclusion: AIP is a challenging disease for diagnosis and treatment. Cortisone treatment is generally successful and provides clinical remission in the large majority of patients. In the further course of the disease, the number of patients develop PEI (up to 60% of pts) and diabetes (up a quarter of pts). Only a quarter of patients exhibit the characteristic “sausage-like” pancreas, approximately 40% had a focus mass that can be misdiagnosed as pancreatic malignancy.

Disclosure: Nothing to disclose

P0104 DEFICIENCY OF FAT-SOLUBLE VITAMINS, MINERALS AND TRACE ELEMENTS IN PATIENTS WITH CHRONIC PANCREATITIS OF DIFFERENT ETIOLOGY

1Karolinska University Hospital, Department for Digestive Diseases, Stockholm, Sweden
2European Institute of Oncology, Division of Epidemiology and Biostatistics, Milano, Italy

Contact E-Mail Address: mvuisay@gmail.com

Introduction: Malnutrition with deficiencies of fat-soluble vitamins and trace elements are well-known consequences of maldigestion and poor absorption of nutrients, and have been frequently identified in patients with pancreatic exocrine insufficiency (PEI). The prevalence of abnormal laboratory nutritional markers in chronic pancreatitis has been investigated in several studies, but most of them were restricted to patients with alcoholic chronic pancreatitis (CP) and had limitations due to the small number of patients. We are presenting results of the largest study so far comparing markers of malnutrition in relation to different etiological groups of CP.

Aims and Methods: We performed a retrospective analysis of medical records of patients with CP. Etiology of CP was determined according to M-ANNHEIM classification. The following demographic, clinical and demographic parameters were analyzed: age, gender, smoking (pack years), consumption of alcohol (units per day/years), fecal elastase-1 (FE1), albumin, calcium, magnesium, iron, triglyceride, cholesterol, hemoglobin, vitamin A, vitamin E, vitamin D and zinc.

Results: Altogether, 226 patients were included in the analysis: 131 (58.0%) male and 95 (42.0%) female, mean age 51.8 ± 17.9 years (range 18–89). The different etiologies of CP comprised: autoimmune (n = 69; 30.5%), alcohol (n = 65; 28.8%), efferent duct factors (n = 20; 8.8%) and idiopathic (n = 27; 12.0%). FEI was normal (FEI > 200mg/g) in 83 (41.7%) patients. Mild to moderate PEI (FEI 100–200mg/g) was found in 22 (11.1%) of patients and severe PEI (FEI < 100mg/g) in 94 (42.7%) of patients. Prevalence of deficiencies in serum nutritional panel was as follows: vitamin D 51.3%, albumin 34.2%, zinc 26.0%, hemoglobin 15.8%, cholesterol 14.1%, cobalamin 11.0%, iron 10.5%, vitamin A 8.3%, vitamin E 6.9%, magnesium 14.7%, folate 4.4%, 1,25(OH)2D3 11.5% and calcium 0%, with no statistical significant differences between nutritional deficiencies and different etiologies of CP. Factors associated with low zinc values were age > 70 years (p = 0.003) and current smoking status. (p = 0.02). Factors associated with low vitamin D levels were age > 60 years (p = 0.03), male gender (p = 0.007), insulin treated diabetes mellitus (p = 0.05) and severe PEI (p = 0.05). In patients who bone mineral density was performed, 21 (24.1%) of patients had osteopenia and 9 (10.3%) osteoporosis.

Conclusion: A large number of CP patients exhibits signs of malnutrition with vitamin deficiencies. Deficiencies of fat-soluble vitamins, minerals and trace elements appear not to be related to CP etiology. Noteworthy, more than a third of patients had a focus mass that can be misdiagnosed as pancreatic malignancy.

Introduction: Previous reports showed pancreatic atrophy 6 months after the initiation of steroid therapy with diabetes control worsening and incidence of new onset of diabetes in patients with autoimmune pancreatitis (AIP). However, predictor for pancreatic atrophy after steroid therapy at the diagnosis of AIP remains unknown.

Aims and Methods: We aimed to evaluate the role of equilibrium computed tomographic (CT) imaging for the prediction of pancreatic atrophy 6 months after steroid therapy. 33 steroid treated AIP patients, who underwent CE-CT examinations before and after steroid therapy, were included in this study during December 2005 to October 2015. CT attenuation (Hounsfield units [HU]) values in noncontrast (NC) and equilibrium phase (EP) images were measured by placing 3 regions of interest (ROIs) from the anterior to the posterior part of the organ. The degree of difference of each HU value with the degree of atrophy was evaluated.

Results: Pancreatic atrophy was observed in 11 patients and not in 22 patients after the steroid therapy. Pancreatic atrophy was not associated with the thickness of pancreatic body on CE-CT before steroid therapy, other organ involvement, pattern of pancreas swelling (diffuse/focal) and serum IgG4 levels. The HU values in NC and EP subtracted HU values in AIP with atrophy were significantly higher than those without atrophy (113.2 ± 16.1 vs. 100.0 ± 11.8, p = 0.01, 70.7 ± 18.0 vs. 57.8 ± 13.9, p = 0.03). Thickness of pancreatic body after steroid therapy was also associated with HU values in EP and subtracted HU values (less than 10–15mm: median 13.5 ± 10mm vs. 70.6 ± 9.2, 92.7 ± 10.9, p = 0.002, 70.7 ± 18.0 vs 63.6 ± 11.7: 50.4 ± 13.5, p = 0.01).

Conclusion: Equilibrium contrast CT imaging at the diagnosis of AIP would be a potential predictor for pancreatic atrophy after steroid therapy. The use of other therapies, such as immune-modulating agents, might be recommended for those patients.

Introduction: Fatty pancreas (FP) is an increasingly recognised entity associated with obesity and the metabolic syndrome. It correlates with non-alcoholic fatty liver disease (NAFLD) and progression to cirrhosis. It is hypothesised that a similar process exists resulting in chronic pancreatitis, fibrosis and pancreatic exocrine insufficiency (PEI) with associated malnutrition-related complications; such as vitamin D deficiency and impaired bone metabolism.1,3 FP as a cause of PEI has not been thoroughly assessed, with published studies largely comprising small case reports.4–5

Aims and Methods: This study assessed the relationship between FP and PEI, by examining the correlation with impaired bone metabolism. Cases were identified by a search of computed tomography (CT) reports from January 1st, 2010 to June 30th, 2017 at Melbourne Health, using keywords of FP and its synonyms; including pancreatic lipomatosis, fatty replacement or infiltration of the pancreas, lipomatous pseudo-hypertrophy of the pancreas, and pancreatic steatosis.6 Controls were identified using keywords of normal pancreas. All images were reviewed by a radiologist to confirm CT report diagnoses. Retrospective clinical data was obtained from existing medical records and pathology. Data of interest included features of impaired bone metabolism, namely osteopenia and osteoporosis. Patients without available medical records were excluded. Cases and controls were assessed for baseline characteristics, including gender and age. Outcomes of impaired bone metabolism were assessed as categorical variables and statistical analysis undertaken on identified trends. Chi-square test for independence was used with a statistical significance level of p < 0.05; Fisher's exact test was used for small sample sizes with a statistical significance level of p<0.05. Sub-analyses were completed to remove confounding variables of age and gender.
Results: 133 cases and 117 controls were identified. There were no statistically significant differences in gender distribution or age between the cohorts. Both groups comprised 59% males. The mean age of cases and controls was seventy-seven years and sixty-seven years respectively [case range 43–99 years; control range 42–94 years; \( p = 0.15 \)]. There was a statistically significant difference in impaired bone mineral density (BMD) between cases and controls in 41.4% and 20.5% respectively [OR 2.73, RR 2.02]. This difference was independent of gender [males OR 3.53, RR 2.65; females OR 2.28, RR 1.63] and age greater than sixty-five years [total OR 2.83, RR 2.02; males OR 3.44, RR 2.53; women greater than 65 years demonstrating a positive trend without statistical significance [OR 2.19, RR 1.56].

Conclusion: The study showed a statistically significant relationship between incidental FP and impaired bone metabolism with a RR of 2.02. This was independent of gender and increased age, except with women greater than 65 years of age showing a positive trend but no statistical significance. This suggests that FP is not a benign finding and is associated with PEI. Recognising these patients is of clinical importance, as early detection and treatment of PEI may improve the associated morbidity and mortality.

Disclosure: Nothing to disclose.

P0107 METABOLIC BONE DISEASE IN CHRONIC PANCREATITIS; A SINGLE-CENTRE EXPERIENCE

F. Rana, N. Bekkal, R. Charnley, J. Logue, M. Nayar, K. Oppong, J. Leeds
Freeman Hospital, Newcastle, United Kingdom

Contact E-Mail Address: fahdrana@outlook.com

Introduction: Chronic pancreatitis is associated with metabolic bone disease which increases the risk of fracture. The National Institute of Clinical Excellence (NICE) guidance recommends that all patients aged 50 or over should be considered for DEXA scanning at risk (1). Previous data has shown under-utilisation of DEXA scanning in this population despite increased risk of osteoporotic fracture. The primary aim of this study was to assess compliance with metabolic bone assessment in patients with chronic pancreatitis, assess the prevalence of abnormal DEXA scans and the impact of this assessment on appropriate management.

Aims and Methods: Retrospective analysis of outpatient coding for “chronic pancreatitis” during 2017 from Freeman Hospital. DEXA scan results were retrieved for chronic pancreatitis patients from the radiology department. Aetiology recorded as alcohol (n = 52), idiopathic (n = 25), autoimmune (n = 4), hereditary (n = 3), anatomical (n = 1) and biliary (n = 102). Patients were also assessed for the prescription of bone protection. Those not requiring pancreatin replacement therapy (PERT) (n = 201) were included with aetiology recorded as alcohol (n = 52).

Conclusion: The study found that the impact of DEXA scanning on prescription of bone protection was also assessed. The impact of DEXA scanning on prescription of pancreatic enzyme replacement therapy (PERT) and osteoporosis treatment was investigated in patients with chronic pancreatitis, assessing the prevalence of abnormal DEXA scans and the impact of this assessment on appropriate management. The study found that DEXA scanning was underutilised in chronic pancreatitis patients compared to the general population. Abnormal DEXA scans were significantly associated with appropriate prescription of bone protection.

Disclosure: Nothing to disclose.

P0108 DIFFERENCES IN IMAGING STUDY BETWEEN LOCALIZED AUTOIMMUNE PANCREATITIS AND PANCREATIC CANCER: A MATCHED CASE-CONTROL STUDY

Teine Keijinkai Hospital, Center for Gastroenterology, Sapporo, Japan

Contact E-Mail Address: kin_toshihumi@yahoo.co.jp

Introduction: Although the differential diagnosis between autoimmune pancreatitis (AIP) and pancreatic cancer (PC) is important in clinical settings, it is difficult to distinguish PC and localized type AIP which mimics PC in clinical presentation. However, the difference in imaging study between them has not been fully discussed.

Aims and Methods: The aim of this study was to compare the imaging findings between localized AIP and PC. 81 patients were diagnosed as AIP by International Consensus Diagnostic Criteria (ICDC) from April 2007 to October 2017, and 22 of them who showed the focal enlargement in pancreatic imaging were analyzed retrospectively (Group AIP; definitive 18, probable 4). During the same period, 191 patients were diagnosed as PC after surgical resection, and 44 of them were selected as a control (Group PC) in this study. To minimize the selection bias, the patients in Group PC was extracted by 1:2 ratio optimal matching, which was adjusted for age, gender, mass location, tumor size using propensity score. Measured outcomes were the findings of contrast enhanced CT, MRCP, and EUS. The statistical evaluations were conducted using Mantel-Haenszel test.

Results: Median ages of Group AIP and PC were 69 (range, 49–80) and 71 (range, 49–82) years old, respectively. The male to female ratios of them were 57:28 and 26:18. The mass location and the patients in Group AIP was pancreatic head in 11 and body/tail in 11 while that of the patients in Group PC was pancreatic head in 22 and body/tail in 22. Median tumor sizes of them were 21 (range, 5–40) and 23 (range, 10–23) mm. On CT imaging, the rates of the patients with high attenuation lesion in equilibrium phase or apparent capsule like rim were not different between Group AIP and PC (95% vs. 98%; 95% vs. 2%). However, a high attenuation lesion as compared to normal pancreatic parenchyma in equilibrium phase was observed more in the patients of Group PC (27% vs. 55%, \( p < 0.007 \)). More than half of main pancreatic duct (MPD) dilation was also noticed more in the patients in Group PC (27% vs. 64%, \( p = 0.008 \)). MRCP was carried out to 19 patients of Group AIP and matched 30 patients of Group PC. Among them, MRCP stricture at the lesion was observed in 84% of Group AIP and 80% of Group PC. However, MRCP stricture apart from the lesion was also included in 53% of Group AIP and 7% of Group PC, which showed a significant difference between them. As for EUS, the significant differences were not present in the findings regarding the boundary or echogenicity of the lesion. Moreover, the presence of hyperchoic foci inside the lesion was observed more in the patients of Group AIP (91% vs. 7%, \( p < 0.007 \)).

Conclusion: While a high attenuation tumor in equilibrium phase or more than 4mm of MPD dilation on CT were observed more frequently in PC, specific findings of MRCP was the MRCP stricture apart from the lesion on MRCP and presence of hyperchoic foci inside the lesion on EUS.

Disclosure: Nothing to disclose.
is to understand the modifying effect of the number of acute episodes which contribute to CP. The Hungarian Pancreatic Study group has built up a prospective register of subjects with AP. In the last 6 years, precise clinical data were collected from 1435 patients. In this study, data on the number of episodes from 1315 patients with high data accuracy were analyzed.

**Results:** In our cohort, 983 (74.75%), 270 (20.53%), 62 (4.72%) patients had a single episode of AP, ARP, and CP, respectively. In the ARP group, 173 patients (64.07%) had 2 episodes, 43 (15.93%) had 3 episodes, 24 (8.89%) had 4 episodes, and 30 (11.11%) had 5 or more episodes. 13 biomarkers were significantly different between AP, ARP, and CP. The significant difference between AP and CP disappeared after the second episode of AP concerning 8 biomarkers (gender, age, biliary etiology, alcohol consumption, pseudocyst development, gammaGT, amylase, and red blood cell count), as did after the third episode concerning 3 biomarkers (gender, body mass index, ASAT) as did after the fourth and fifth episodes concerning 2 biomarkers (ALAT and smoking). As an average, the significant differences between AP and CP disappeared from 2.63 attacks. The average number of acute episodes of patients with pre-existing morphological alterations in the pancreas is to understand the modifying effect of the number of acute episodes which contribute to CP. The Hungarian Pancreatic Study group has built up a prospective register of subjects with AP. In the last 6 years, precise clinical data were collected from 1435 patients. In this study, data on the number of episodes from 1315 patients with high data accuracy were analyzed.

**Conclusion:** A definition of early CP may be 3 or more previous attacks of AP without chronic morphological alterations in the pancreas.

**Disclosure:** Nothing to disclose.
Introduction: Pancreatic ductal adenocarcinoma (PDAC) is one of the most frequent gastrointestinal cancers and the fourth leading cause of cancer-related death. Despite several new developed anti-cancer drugs, the survival rates in advanced stages remain disappointing. Thus, innovative therapeutic approaches are urgently needed. On molecular levels, oxidative stress (ROS) is important for the development and progression of the disease. There was, highly reactive compound methylglyoxal (MGO) is an important source for ROS. MGO is a by-product of glycolysis and mainly detoxified by Glyoxalase-I (Glo-I). Overexpression of Glo-I has been shown in different tumours and linked to multi drug resistance in cancer therapy. Until now, the importance of Glo-I in PDAC has not been elucidated. Thus, we analysed the role of Glo-I for proliferation, migration and colony formation in PDAC.

Aims and Methods: Expression of Glo-I was determined in 7 PDAC cell lines (BxPC3, Capan-1, Capan-2, CFPPAC, HS776T, MiaPaca2, Panc-1) via immunocytochemistry (DAB-staining) by means of Cytospin centrifugation. Analysis of cell proliferation (Wst-assay), migration (scratch assay) and colony formation (clonogenic assay) was performed in all cell lines and correlated to Glo-I expression.

Results: HS776T and MiaPaca2 cells showed highest expression of Glo-I. Capan-2 and CFPPAC revealed low Glo-I staining intensity whereas BxPC3, CFPAC and HS776T exhibited average Glo-I expression. Interestingly, HS776T and MiaPaca2 also showed highest rates of proliferation and colony formation but not migration. In contrast, Capan-2 and CFPPAC revealed minor proliferation and colony formation but only CFACP indicated high cell migration. Proliferation, migration and colony formation of BxPC3, Capan-1 and Panc-1 was at average levels.

Conclusion: Glo-I is expressed in all examined PDAC cell lines. High expression of Glo-I was positively correlated with proliferation and colony formation but not migration. Ongoing studies analyses the effects of Glo-I knockdown, overexpression and pharmacologic inhibition will further elucidate the role of Glo-I for proliferation, migration and colony formation of BxPC3, Capan-1 and Panc-1 was at average levels.

P0117 CLINICOPATHOLOGICAL FEATURES OF PancreATIC ductAL AdENOCARCINOMA CoNCOMITANT WITH INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS OF THE PanCREAS

Sendai City Medical Center, Department of Gastroenterology, Sendai, Japan
Sendai City Medical Center, Department of Surgery, Sendai, Japan
Sendai City Medical Center, Department of Pathology, Sendai, Japan

Contact E-Mail Address: yajiro.yawasaki@gmail.com

Introduction: Although intraductal papillary mucinous neoplasms of the pancreas (IPMNs) have been recognized as precursor lesions for pancreatic cancer, it has been reported to be associated with pancreatic ductal adenocarcinoma (PDAC) that does not occur from IPMN lesions (concomitant PDAC, C-PDAC). The clinicopathological features of C-PDAC have not been clarified in comparison to other types of pancreatic adenocarcinoma.

Aims and Methods: This study was performed to elucidate the clinicopathological features of C-PDAC. Of the 43 patients histologically confirmed to have pancreatic invasive adenocarcinoma by using resected specimens, EUS-FNA, or endoscopic biopsy at our center between January 1985 and December 2016, 91 patients with C-PDAC were included in this study and retrospectively analyzed. The occurrence rate of C-PDAC and clinicopathological features of C-PDAC were compared with that of IPMN.

Results: The occurrence rate of C-PDAC was 29% (47/161) in resection cases and 16% (4/24) in non-resection cases. The presence of IPMN was diagnosed by using resected specimens in 47 resection cases and by using imaging examinations in 44 non-resection cases. The outcome measurements were defined as (1) the rate of C-PDAC patients among all IPMN patients (C-PDAC + IPMN) and (2) the clinicopathological features of C-PDAC (group A, n = 47) in comparison to those of PDAC without IPMN (group B, n = 105) and those of invasive cancer derived from branch duct IPMN (group C, n = 27) in resected cases.

Results: The percentage of C-PDAC was 29% (47/161) in resection cases and 16% (4/24) in non-resection cases. There was no significant difference in any factors investigated, such as age, sex, history of acute pancreatitis or diabetes mellitus, pathological stage, and survival period after surgical resection, between groups A and B. Between groups A and C, the pathological stages (stage IA, 6% vs. 33%, p = 0.004) and survival period after surgery (mean, 1368 vs. 2567 days, p = 0.044) were significantly different. As to morphological findings on the accompanying IPMN in groups A and C, there was significant difference in the cyst size (171 ± 10.6 mm vs. 44.1 ± 21.0 mm, p < 0.001), multifocal
P0118 AN EXAMINATION OF THE USEFULNESS OF MASPIN STAINING IN EUS-FNA SAMPLES FOR PANCREATIC CANCER
Dokkyo Medical University, Tochigi, Japan
Contact E-Mail Address: d-fuku-k@dokkyomed.ac.jp
Introduction: There are many reports that KRAS and p53 are useful in improving the diagnostic yield of endoscopic ultrasound-fine needle aspiration biopsy (EUS-FNA) for pancreatic tumors. Nevertheless, KRAS and p53 are often negative if structurally, the tumor is anaplastic or the sample amount is small. On the other hand, Maspin which is serine protease inhibitor, is recently attracted as a new gene marker of pancreatic cancer.
Aims and Methods: The aim of this study was to evaluate the usefulness of Maspin staining in histopathological diagnosis using EUS-FNA. 94 patients who performed both Maspin and p53 staining in specimen obtained by EUS-FNA were enrolled in this study. All patients were diagnosed as the pancreatic adenocarcinoma at Dokkyo medical university hospital using EUS-FNA in the period from April 2015 to December 2017. We evaluated positive rate of Maspin and/or p53, and the relationship between immunohistochemistry and clinical factors (sex, age, location, size, tissue differentiation, rate of metastasis, Maspin positive rate, and tumor biomarker).
Results: The positive rates were 72.4% (71/98) in p53, 98.0% (96/98) in Maspin. There was no statistically significant difference between p53 positive and negative cohorts, but Maspin was positive in all cases of the p53 negative cohort. On the other hand, there was statistically significant difference between Maspin positive cohort and the negative cohort in age (70.5 vs. 53.0, p = 0.026) and the revel of SUV (10 vs. 2.0, p = 0.023). In addition, p53 was positive in 2 cases where Maspin was negative.
Conclusion: The expression of Maspin was higher than p53 in pancreatic adenocarcinoma. Our study suggested that the immunostaining combined p53 and Maspin would contribute to the improvement of diagnostic yield for pancreatic tumor using EUS-FNA.

P0119 DIAGNOSTIC USEFULNESS OF LOCALIZED STENOSIS OF THE MAIN PANCREATIC DUCT FOR DETECTION OF EARLY PANCREATIC CANCER
Sendai City Medical Center, Sendai, Japan
Contact E-Mail Address: yoshi-hk@openhp.or.jp
Introduction: Although early detection of pancreatic cancer is associated with a better prognosis, it has been extremely difficult to detect. Localized stenosis of the main pancreatic duct (MPD) often indicates early pancreatic cancer, including intraductal cancer.
Aims and Methods: The aim of this study was to evaluate the predictive sensitivity of localized MPD stenosis for the detection of pancreatic cancer. Among 597 patients who underwent intentionendoscopic retrograde pancreatography (ERP) between January 2008 and December 2017 at Sendai City Medical Center, those in whom ERP was performed to evaluate abnormal findings on the MPD were extracted from the prospectively maintained database. Those with multiple MPD stenoses, diffuse MPD dilation, and a mass detectable on other imaging examination, were excluded. Those with other pancreatic diseases, such as intraductal papillary mucinous neoplasms (IPMN), autoimmune pancreatitis (AIP), and definite chronic pancreatitis were also excluded. Finally, 17 patients with a single, localized stenosis in the MPD without a mass (defined as the typical MPD findings for suspicious early pancreatic cancer [TF-EPC]) were included in this study.
Final diagnosis of the etiology causing the MPD stenosis was defined as being (1) malignant or benign by histological diagnosis with a surgically resected specimen when the tumor was resected, (2) malignant when an obviously malignant tumor appears at the site during follow-up if resection was not performed, or (3) benign when the abnormal findings improved or did not change on imaging examinations (EUS, CT, MRI or ERCP) after a 3-year follow-up without resection.
If the findings were difficult to define, whether they changed or not, the patients were excluded. The main outcome measurement was the predictive sensitivity of the TF-EPC for the presence of pancreatic cancer.
Results: Of the 9 patients who underwent surgical resection among the analyzed patients, the final diagnosis of the MPD stenosis was judged as pancreatic cancer in 8 patients and as a non-neoplastic change in 1 patient. In the remaining 8 patients, the MPD stenosis was judged as being non-neoplastic by performing clinical follow-up of > 5 years (mean follow-up period, 2186 ± 415 days). Overall, the final diagnosis of the MPD stenosis with the TF-EPC was pancreatic cancer in 8 patients (47%) and a non-neoplastic change in 9 patients. In other words, the predictive sensitivity of the TF-EPC for presence of pancreatic cancer was 47%. Of the 8 patients with pancreatic cancer, 3 were diagnosed as having primary pancreatic adenocarcinoma and the other 5 patients were diagnosed with ductal adenocarcinoma. The size of the invasive mass was less than 10 mm in all 5 patients with invasive cancer (mean diameter, 7.0 ± 0.9 mm). The specificity, sensitivity, and accuracy of cytology by using pancreatic juice obtained during ERP with cell-block preparation was 100%, 90%, and 88%, respectively.
Conclusion: MPD stenosis with typical findings for suspicious early pancreatic cancer, which was defined as a single, localized stenosis without other pancreatic diseases with no mass detectable on imaging examination, was derived from pancreatic cancer in half of the patients. Such findings were found to be useful for detecting early pancreatic cancer, although histological confirmation using pancreatic juice cytology would be necessary before surgical resection.

Introduction: About 5% of pancreatic ductal adenocarcinoma (PDAC) are inherited, with a deleterious germline mutation detected in ≥ 20% of families. Pancreatic screening in high-risk individuals (HRIs) is proposed to perform early surgical treatment of malignant lesions, such as pancreatic intraepithelial neoplasia [PanIN] or intraductal papillary mucinous neoplasms [IPMN] with high-grade dysplasia, or even invasive PDAC at an early stage. Performing surgery in HRI at the optimal time, i.e., neither too early (non-malignant lesions) nor too late (advanced PDAC), remains challenging. The outcomes of pancreatic surgery in HRI have never been properly explored.
Aims and Methods: We aimed to evaluate surgical appropriateness and explore predictive factors in screened HRI who underwent pancreatic surgery. A patient-level meta-analysis was performed on all studies reported since 1999 who included HRI defined by strict criteria and described individual screening, surgical and pathological data of operated HRI.
For each operated HRI, the highest risk pancreatic abnormality identified at screening was classified into low-risk abnormality [LRA] (cyst with benign features) or high-risk abnormality [HRA] (cyst with worrisome features or high-risk stigmata of malignancy, solid mass and/or sample positive for malignancy). The highest malignant pathological lesion was classified into no/malignant potential (branch-duct IPMN or PanIN with low-grade dysplasia) or potentially/frankly malignant (branch-duct IPMN or PanIN with high-grade dysplasia) or potentially/frankly malignant PDAC.
Surgical appropriateness was considered when potentially/frankly malignant lesions were resected. Univariate and multivariate logistic regression models of factors predictive of surgical appropriateness were performed. The variables of the multivariate model were used to establish a score and nomogram allowing the estimation of individual probability of surgical appropriateness.
Results: 13/24 studies were selected, which reported 90 HRI operated on. LRA and HRA were detected in 46.7% and 53.3% of HRI, respectively. Surgical appropriateness was consistent in 38 (42.2%) HRI operated, including 20 HRI (22.2%) with PDAC. Identification of HRA at screening was the only factor associated with surgical appropriateness at multivariate analysis (p = 0.001). We proposed the Beaujon score, including the identification of HRA, age ≥ 50 and the existence of deleterious germline mutation. The score was used to build a nomogram which predicted individual surgical appropriateness with an area under the curve of 0.81.
Survival data were available for 66 operated HRI. After a median postoperative follow-up of 29 months, 9 HRI died, including 8 who were operated on for invasive PDAC. HRI with invasive PDAC had a significantly lower overall survival (median, 35 months) compared to HRI with other pathological results (p < 0.0001).
Conclusion: Overall, 42.2% of HRI underwent appropriate surgery. Surgical appropriateness was higher in HRI with HRA identified at screening. We proposed the Beaujon score to help selecting the best candidates for pancreatic resection. This score requires prospective validation.

P0122 PREDICTION OF LIVER METASTASIS AFTER SURGICAL RESSECTION OF ENDOCYTIC DUCTAL CARCINOMA OF THE PANCREAS BASED ON PREOPERATIVE ENDOCYTIC ULTRASOUNDOGRAPHY FINDINGS AND PATHOLOGICAL EXAMINATION

Y. Hamada, D. Kato

Fukuoka University, Department of Pathology, Fukuoka, Japan

Contact E-Mail Address: yoshiihiro42@me.com

Introduction: The poor prognosis after surgical resection of invasive ductal carcinoma of the pancreas (IDCP) is due to the high recurrence rate. IDCP usually recurs in the liver and at local sites, such as the pancreatic bed or adjacent structures. Notably, the survival duration among patients with liver metastasis (LM) is ≤3 years after R0 resection, even when the diameter of the IDCP is <2 cm (pTS1). We analysed patients with pTS1 IDCP and found that the median number of invading veins in the area of the IDCP was 5 and 2 in patients with and without LM [1], respectively. However, frequent venous invasion by the carcinoma and cancer cell migration into the bloodstream had already occurred at the time of surgical resection, particularly in patients with LM. Thus, measures should not only undergo surgical resection but also prepare for LM. Patients with IDCP with a vague periphery as demonstrated by EUS invasion and recurrence [2]. We analysed the correlations among LM, venous invasion, tumour growth patterns, and endoscopic ultrasonography (EUS) findings in patients with pTS1 IDCP.

Aims and Methods: Of 402 patients with IDCP, 21 (5.2%) had pTS1 tumours. The follow-up period among these 21 patients ranged from 6 months to 25 years. All patients underwent R0 resection. Handling of the surgical specimen and assessment of vascular permeation by the carcinoma were performed as previously described [1,3]. Clinicopathological factors were assessed according to the Classification of Pancreatic Carcinoma (4th English edition) by the Japan Pancreas Society. The tumour growth pattern of neoplasms infiltrating surrounding tissue (INFα, expanding growth; INFc, diffusely infiltrating pattern; INFb, in between INFα and INFc) was assessed by loupe findings of the maximum cut surface of the IDCP. EUS findings were evaluated with respect to morphology.

Results: The 21 patients comprised 12 men and 9 women aged 51 to 80 years. 5 patients died of liver metastasis. Among 14 patients who underwent EUS, 4 patients with LM exhibited worrisome imaging features of hepatocellular carcinoma on computed tomography and magnetic resonance imaging were recently shown to correlate with microvascular invasion and recurrence [2]. We analysed the correlations among LM, venous invasion, tumour growth patterns, and endoscopic ultrasonography (EUS) findings in patients with pTS1 IDCP.

Conclusion: Patients with IDCP with a vague periphery as demonstrated by EUS should not only undergo surgical resection but also prepare for LM.

P0123 ROLE OF RAPID ON SITE EVALUATION (ROSE) FOR ENDOCYTIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION (FNA) OF SOLID PANCREATIC LESIONS: “ON SITE” MULTIDISCIPLINARY TEAM IS MORE IMPORTANT THAN TECHNIQUE FOR AN ACCURATE DIAGNOSIS

N. Olivari, S.M. Milluzzo, M. Graffeo, M. Lovera, D. Bianchi

Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy

Contact E-Mail Address: nicola.olivari@tiscal.it

Introduction: EUS-FNA is the first-line technique for sampling pancreatic lesions. It is regarded as safe procedure but many factors influence adequacy and accuracy, among the others presence of the cytopathologist and the real time evaluation and analysis of the specimens.

Aims and Methods: This is a retrospective analysis of patients who underwent EUS-FNA for known pancreatic solid lesions before and after ROSE adoption. All consecutive EUS-FNA procedures for pancreatic lesions performed during the first year of adoption (ROSE1 group) and the following year (ROSE2 group) were compared to those performed during the previous year (pre-ROSE group). EUS was performed using a linear echoendoscope. FNA was performed using fine needles 22 or 25 Gauge diameter. Demographics, lesion location and size, number of needle passes, final diagnosis were recorded. The gold standard for diagnosis was considered histological analysis of surgical specimen, when available, or clinical and radiologic follow up compatible with neoplasia (positive) or absence of deterioration/spontaneous resolution (negative). Specimen were categorized into diagnostic if a final diagnosis was reported and non diagnostic in case of no sufficient cells or when atypia was not further classified. Adequacy (samples providing sufficient material for evaluation), diagnostic yield (rate at which a diagnosis is made), diagnostic accuracy (correspondence between cases for which a diagnosis was rendered and the gold standard) were evaluated. Aim of the study was to compare the adequacy, diagnostic yield and accuracy of EUS-FNA for solid pancreatic lesions before and after introduction of ROSE.

Results: 94 pancreatic lesions in 92 patients were enrolled (26, 30 and 38 in pre-ROSE, ROSE1 and ROSE2 groups respectively). Adequacy rate was 96.2%, 93.3% and 100% in pre-ROSE, ROSE1 and ROSE2 groups, respectively (p = NS). Diagnostic yield was 76.9%, 86.7%, 92.1% and accuracy 65.4%, 76.7% and 86.8% in pre-ROSE, ROSE1 and ROSE2 groups, respectively, with significant difference between pre-ROSE and ROSE2 groups (p<0.05).

Conclusion: The routine use of ROSE during EUS-FNA for solid pancreatic lesions is associated with an improvement in terms of diagnostic yield and accuracy, but it does not seem to improve the adequacy of FNA. Lack of difference during the first year of adoption of ROSE was probably due to the learning curve of the multidisciplinary team.

P0124 WATER-POCKET ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL GASTRIC NEOPLASMS: A PROSPECTIVE RANDOMIZED STUDY
New Tokyo Hospital, Gastroenterology, Chiba, Japan

Contact E-Mail Address: nerimaendo@hotmail.co.jp

Introduction: It is essential to obtain a clear view during the endoscopic submucosal dissection (ESD) to precisely dissect the appropriate submucosal layer. Several variations of underwater techniques for gastric ESD have been reported in comparison with gas insufflation method [1, 2]. We have developed a new ESD method with the creation of a local water-packet that provides a clear view in the dissection field. Therefore, we aimed to investigate the feasibility and safety of water-pocket ESD (WP-ESD) for superficial gastric neoplasms.

Aims and Methods: We prospectively recruited 50 patients with gastric neoplasms (early gastric cancer or gastric adenoma) between April 2017 and December 2017. Among them, 48 patients were treated with WP-ESD technique. The patients with WP-ESD were compared with 48 patients treated with standard ESD (S-ESD) who were selected by propensity score matching. The primary outcome was the ESD procedure time.

The rationale of the WP-ESD technique is that ESD procedure is carried out underneath the target lesion via a locally created water pool in the submucosal layer. First, to create a submucosal pocket, an initial incision is made approximately 2 cm proximal to the lesion. Second, the tip of the attached transparent ST hood is inserted into a small hole followed by injection of saline solution, and dissection of the submucosal layer is initiated in the water pool.

The study protocol was approved by the ethics committee of New Tokyo Hospital (IRB No. NTH 0112) and was registered in the University Hospital Medical Network Trials Registry (UMIN00030266).

Results: Total procedure time was significantly shorter in the WP-ESD group than in the S-ESD group (median [IQR], 27.5 [19–43] min vs. 41 [29.8–69] min; p < 0.001). Similarly, the dissection speed was significantly greater in the WP-ESD group than in the S-ESD group (median [IQR], 22.5 [16.8–35.3] mm²/min vs. 17.3 [12.7–22.1] mm²/min; p < 0.001). The rates of complete en bloc resection in the WP-ESD group and the S-ESD group were 97.9% and 95.8%, respectively (p = 0.36). The median maximum diameter of iatrogenic duodenal perforations ≥ 1 cm were retrospectively studied who were respectively treated by purse-string sutures using the novel LeCamp™ endoloops and the SureClip™ repositionable hemostasis clips with the single-channel endoscope at 4 institutes.

Conclusion: WP-ESD was associated with a shorter procedure time than S-ESD. WP-ESD may provide an alternative method for resection of superficial gastric neoplasms.

Disclosure: Nothing to disclose.

Introduction: With the development and maturation of endoscopic resection, endoscopic full-thickness resection (EFR) derived from endoscopic submucosal dissection (ESD) is gradually accepted and promoted to treat submucosal tumors (SMT) originating from muscularis propria (MP) layers. However, there are some difficulties when EFR is applied in the treatment of muscularis propria lesions in gastric fundus. This study intends to explore whether EFR can be more simple, safe and effective with the traction assistance of dental floss.

Aims and Methods: To assess modifications in anaesthesia practices for POEM. Preoperative Measures: Clear liquids and lukewarm water 24 hours before. Thorough pre anesthesia work up. Induction of anaesthesia and intraoperative management: POEM procedures were carried out under general anaesthesia with endotracheal intubation and positive pressure ventilation to reduce the risk of capno diastasis. One assistant is kept ready for Selliks manoeuvre and suctioning of the oral cavity if patient aspirates the fluid in the esophagus. Anesthesia in all the patients was induced by rapid sequence method (to prevent aspiration of esophageal content). Sedation and induction was achieved by (Inj. Glycopyrrolate 0.2 mg; Midazolam 0.02 mg/kg; Propofol-1-2mg/kg; Fentanyl 100mcg; Succinylcholine 1-2 mg/kg). Atraumatic endo-clip using the novel LeCamp™ endoloops and the SureClip™ repositionable hemostasis clips with the single-channel endoscope at 4 institutes.

Conclusion: None to disclose.

Introduction: Serious complications due to perforations restrict the development of duodenal endoscopic treatment. The key stage for remediation is the successful occlusion to prevent peritonitis and the need for surgical intervention. This report presents a new simple method for the closure of large iatrogenic duodenal perforations with purse-string sutures using the novel endoloops and repositionable clips through a single-channel endoscope.

Aims and Methods: A total of 23 patients with iatrogenic duodenal perforations ≥ 1 cm were retrospectively studied who were respectively treated by purse-string sutures using the novel LeCamp™ endoloops and the SureClip™ repositionable hemostasis clips with the single-channel endoscope at 4 institutes.

Results: The median maximum diameter of iatrogenic duodenal perforations was 1.65 cm (range 1.0–3.0 cm). Complete closure of all 23 perforations was achieved. No patient had severe complications such as peritonitis. The wounds were healed and no obvious duodenal stricture was observed in all cases at 4 months.

Conclusion: Purse-string sutures using the novel endoloops and the repositionable endoclips through single-channel endoscope were feasible, easy and effective methods for the closure of large duodenal iatrogenic perforations.

Disclosure: Nothing to disclose.

Introduction: Endoscopic submucosal dissection (ESD) in the upper gastrointestinal tract is mostly performed in patients under general anesthesia with endotracheal intubation, especially when the estimated procedure time is likely to exceed two hours [1]. The advantage for using general anesthesia are control of body movements, protection, less respiratory problems or interruptions during the procedure and therefore lower complication rates [2]. However, general anesthesia leads to longer post-procedural hospital stay [3]. Anesthetic complications for general anesthesia reported in the literature are up to 18.9% [2]. Analgo-sedation in the upper gastrointestinal tract is mostly performed in patients under general anesthesia with endotracheal intubation instead of general anesthesia. The aim of this study is to report on the endoscopic and anesthetic complication rates of ESD with propofol sedation.

Aims and Methods: Retrospective cohort study of patients who underwent esophageal or gastric ESD in a tertiary referral center in the Netherlands between October 2013 and February 2018. All patients were sedated by intravenous administration of propofol until the required level of sedation was achieved according to the Ramsay Sedation Scale (score 4 to 5). Remifentanil infusion was started until the required level of analgesia was achieved. Vital signs were continuously monitored during the procedure in the endoscopy room. Primary endpoints were the rates of intra-procedural endoscopy and anesthesia related complications, secondary endpoints were 30-days post-procedural complication rates and the endotracheal intubation conversion rates.

Results: We included 86 patients with a median age of 70 years (range 24–91). 34 ESDs were carried out in the esophagus, 51 in the stomach and 1 in the duodenal bulb. Median lesion size was 25 mm (range 8–120). Median procedure time was 100 minutes (range 15–510). En bloc resection was performed in 77 patients (89.5%), piecemeal resection in 1 patient (1.2%). In 7 patients (8.1%), the procedure was discontinued and no histology was obtained due to muscular invasion (6 cases) or perforation in 1 patient (1.2%). ESD was converted to endoscopic mucosal resection due to bleeding. Early cancer was found in 72/79 patients (91.1%). In 2 patients (2.3%), an intra-procedural endoscopic complication occurred; both bleeding. In 14 patients (16.3%), a post-procedural complication occurred: 5 bleeding (5.8%), 6 retrosternal pain (7.0%), 2 dysphagia (2.3%), 1 stomach pain (1.2%). In 2 patients (2.3%) an intra-procedural anesthetic complication occurred; 1 coughing and in 1 patient hypotension and desaturation. In 2 patients (2.3%), a minor post-operative anesthetic complication occurred; 1 nausea and 1 atrial fibrillation. In 42 patients (48.8%) were discharged the same day, 38 patients (44.2%) were discharged the following day (29 logistic reasons). In 6 patients, hospital stay was > 2 days. Longer hospital stay was not related to anesthesia and no patients were readmitted for anesthesia-related complications.

Conclusion: Propofol-based analgo-sedation without endotracheal intubation is safe for ESD procedures in the esophagus and stomach with low complication rates and short hospital stay.

Disclosure: Nothing to disclose.
group and the Hp-infected group. Among 492 cases of early gastric cancer who underwent endoscopic resection in our hospital between April 2013 and February 2018, the following lesions were excluded: special type gastric carcinoma (gastric adenocarcinoma of the fundic gland type [n = 27], gastric adenocarcinoma with enteroblastic differentiation [n = 4]), and gastric carcinoma with lymphoid stroma [n = 2]). Remnant gastric carcinoma [n = 6], Hp-uninfected gastric carcinoma [n = 20], lesions in which M-NBI has not been performed [n = 2], and lesions without details of Hp eradication (190). The remaining lesions were classified into the Hp-eradicated group (n = 92) and the Hp-infected group (n = 149). Moreover, all cases of the 2 groups were classified into 3 histological subgroups according to Lauren classification: pure intestinal-type/pure diffuse-type/mixed-type. We compared the clinicopathological factors (age, sex, tumor location, tumor size, macroscopic type, invasion depth, lymphatic invasion, venous invasion, horizontal margin, vertical margin, non-neoplastic epithelium, adenocarcinoma with low-grade atypia) and endoscopic findings (the range of mucosal atrophy, demarcation line, microvascular pattern, microsurface pattern).

Results: The Hp-eradicated group was subclassified into 81 cases of pure intestinal-type and 11 cases of mixed-type. There was no case of pure diffuse-type in Hp-eradicated group. The Hp-infected group was subclassified into 131/5/12 cases of pure intestinal-type/pure diffuse-type/mixed type. In comparison between pure intestinal-type of the 2 groups, significantly smaller tumor size (12.5±8.8 mm vs. 16.4±11.4 mm, p<0.05), more depressed lesion (elavated/flat/depressed = 15/3/63 vs. 60/2/69, p<0.01), milder mucosal atrophy (C-1, C-2, 0-1/O-2, 3, 11/30/40 vs. 8/30/93, p<0.01), higher non-neoplastic epithelium covering rate (25/81, 30.9% vs. 19/131, 14.5%, p<0.01) were observed in Hp-eradicated group than in the Hp-infected group. Although DL (+) cases were significantly less in Hp-eradicated group than in the Hp-infected group, DL was detected in most cases in both groups (76/81, 93.8% vs. 130/131, 99.2%, p<0.05). Moreover, DL was detected in all cases of mixed-type in both groups. Whereas, there were no small number of DL (+) cases in pure diffuse-type in the Hp-infected group (2/5, 40%).

Conclusion: M-NBI with MESSDA-G can identify the DL in most patients with pure intestinal-type and mixed-type of early gastric cancer after Hp eradication. Disclosure: Nothing to disclose.

References
tubule-villus mucosal pattern in 80% (p = 0.01 versus other lesions); light blue-crest and regular vascular pattern, thickness and density were absent in all of them. The presence of a regular circular mucosal pattern was more frequently observed in HP and T1-GC compared to adenomas (p < 0.001). The presence of a central erosion with or without demarcation line was more frequently observed in T1-GC (p < 0.001 vs. HP).

[Table 1. *p< 0.012 versus adenoma; †p< 0.003 versus adenoma; ‡p< 0.01; ‡‡p< 0.001]

Conclusion: The NBI analysis of the mucosal pattern seems to be effective to endoscopically discriminate between adenomas and HP while the main characteristic of T1-GC is the presence of a central erosion sometimes with a clear demarcation line. Accordingly, NBI could be an important tool to endoscopically distinguish the histological nature of GPL.

Introduction: Endoscopic submucosal dissection (ESD) for gastric neoplasms was accepted as a standard treatment even in elderly patients. However, it is difficult to obtain clinical outcomes and non-elderly patients because background characteristics are different. Therefore, this study aimed to compare the clinical outcomes between elderly and non-elderly patients by propensity score matching analysis.

Aims and Methods: Early gastric neoplasms treated by ESD between January 2013 and March 2018 at out hospital were retrospectively reviewed. Elderly patients were defined as those aged 75 years old or more. ESD in elderly (ESD-E, n = 58) and ESD in non-elderly (ESD-N, n = 58) were compared. Multivariate analyses and propensity score matching were used to compensate for the differences in age, gender, ASA-score, underlying disease, Anti-thrombotic agent use, tumor size, tumor location, tumor shape, presence of ulcer, differentiation and operator level, which included factors previously reported to affect the outcomes of ESD. Primary outcome was procedure time. Secondary outcomes were the rates of en-block/completion resection and the rates of complications (aspiration pneumonia/perforation/post-procedure bleeding).

Results: Propensity score matching analysis created 58 matched pairs. Adjusted comparison between 2 groups showed similar treatment outcomes (median procedure time: 61.5min vs. 77.5min; p = 0.342; en-block resection rate: 100% in both groups; complete resection rate: 86.8% vs. 97.4%, p = 0.200. However, the rates of complications were higher in ESD-E than those in ESD-N, but not significant. (Aspiration pneumonia: 10.5% vs. 7.9%, p = 1.00; Perforation: 5.3% vs. 0%, p = 0.493, post-procedure bleeding: 2.6% vs. 0%, p = 1.0).

Conclusion: ESD for gastric neoplasms in elderly patients achieved favorable outcomes as well as ESD in non-elderly patients. However, we should take care of complications in ESD for elderly patients.

**P0136 ENDOSCOPIC MUCOSAL RESECTION OF DUODENAL ADENOMAS: SUCCESS, COMPLICATIONS, RECURRENTNESS, AND SURGERY-FREE OUTCOMES IN A UK TERTIARY CENTRE**

R. Lord,1 P. Mundre,2 M. Gold,1 L. Hamshaw,1 J. Kane,1 N. Mohammed1, R. Rembucken1, R. Sood1

1Leeds Teaching Hospitals NHS Trust, NHS Trust, Leeds, United Kingdom
2Bradford Teaching Hospitals NHS Trust, NHS Trust, Leeds, United Kingdom

**Introduction:** Duodenal adenomas consist of sporadic and familial adenomatous polyposis (FAP) associated adenomas. Endoscopic mucosal resection (EMR) is the recognised technique when considering endoscopic removal of these lesions, but outcomes from large studies are lacking. Leeds Teaching Hospitals (LTHT) is a large tertiary centre that has a local catchment area of more than 800,000 people, and to our knowledge this is the largest UK cohort assessing duodenal EMR outcomes.

**Aims and Methods:** Retrospective data collection was performed of all patients who underwent duodenal EMR over a 17-year period at LTHT. We collected data on patient demographics, lesion characteristics and outcomes including significant complications, recurrence and surgery-free survival. Procedures were performed by a single advanced therapeutic endoscopist or an endoscopy fellow under supervision.

**Results:** A total of 98 patients underwent EMR (sporadic n = 23, FAP n = 75). Median adenoma size was 12.5 mm (IQR 9.0–30.0 mm), with 46.9% removed en-bloc. Standard EMR was performed in 87 procedures, and pull-within snare technique in the remaining 11 procedures. Final lesion histology was TA/TVA with LGD (n = 80), TA/TVA with HGD (n = 12), intra-mucosal cancer (n = 3) and in 3 cases data was missing. Patients with FAP were significantly younger with a median age of 49 years (p < 0.001).

The overall complication rate was 12.4%. 1 (1.0%) patient had an intra-procedural bleed which could not be managed endoscopically, delayed bleeding occurred in 6 cases (5.2%) and perforation occurred in 5 cases (5.2%) of which could not be managed endoscopically. Following univariate analysis, “pull-within snare” technique (p = 0.03), piecemeal resection (p = 0.002), increasing polyp size (p = 0.003) were significantly associated with complications. Adenoma recurrence at first follow up was 25.0%.

**Conclusion:** This is the largest cohort in the UK pertaining to duodenal EMR outcomes, with success, recurrence and complications similar to other world-leading endoscopy centres. Adverse outcomes are associated with increasing lesion size, piecemeal resection and EMR technique.

**P0137 A META-ANALYSIS OF SCLEROLIGATION VERSUS BAND LIGATION FOR ERADICATION OF ESOPHAGEAL VARICES:**

S. Abd-Elsalam1, A. Morshed2, H. El-Shirbiny2, M. Fayoud2, O. Marzouk2

1Tanta University, Tropical Medicine Department, Tanta, Egypt
2Kafrelsheikh University, Kafrelsheikh, Egypt

**Contact E-Mail Address:** sherif_tropical@yahoo.com

**Introduction:** Esophageal band ligation (EVL) for esophageal varices has significantly less bleeding rates and complications, and needs a lower number of sessions to achieve eradication of the varices than sclerosis therapy yet has a higher recurrence rate. This is because EVL does not obliterate the deeper varices or perforating veins, whereas the chemical effect of sclerosis therapy does Scleroligation (combined sclerosis and band ligation) has been used successfully for management of esophageal varices and has been recently evaluated in management of gastroesophageal varices.

**Aims and Methods:** We aimed to determine therapeutic efficacy and safety of endoscopic scleroligation and endoscopic band-ligation of esophageal varices. A literature search was conducted in the following medical electronic databases: PubMed, CENTRAL, SCOPUS and Web of Science on the 23rd of December 2017 using the following strategy: scleroligation OR (sclerotherapy AND plus AND ligation) AND (Esophageal varices OR varices). 8 randomized controlled trials from 1996 to 2017 were included in the meta-analysis after tight full text screening. The included studies were analyzed by using RevMan 4.2 software to calculate odds ratio and 95% confidence interval.

**Results:** Of 97 citations discovered by initial search, 8 parallel RCTs were finally included in this meta-analysis. We found that there were significantly less bands used in EVL than in ESL (Chu = 46.80; 95% CI: −3.13 to −1.30; df = 6 (p < 0.0001); F = 87.6%). Compared to ESL, the overall number of sessions to variceal obliteration in ESL was significantly lower (Chu = 571.90; 95% CI: −0.54 to 1.12; F = 99%; p < 0.00001). ESL required fewer weeks of treatment than EVL, further confirming its positive therapeutic effect. Variceal recurrence following ESL was significantly lower than with EVL (Chu = 17.35; 95% CI: 0.97 to 1.09; F = 54%; p < 0.03). Both procedures had the same adverse effects with no significant difference regarding frequency.

**Conclusion:** Endoscopic Scleroligation (ESL) shows high efficacy and safety in management of varices with a low incidence of recurrence.

**Disclosure:** Nothing to disclose

**P0138 CAP-ASSISTED REMOVAL OF IMPACTED ESOPHAGEAL FOOD BOLUS: “THE EASY WAY”**

Cairo University, Internal Medicine, Cairo, Egypt

**Contact E-Mail Address:** dr.mahmoudwahba@gmail.com

**Introduction:** The commonest foreign body impacted in the esophagus in adults is a food bolus [1]. The European Society of Gastrointestinal Endoscopy issued clinical guidelines to deal with this problem in 2016 [2]. It recommends either pushing technique or retrieval methods using one of several accessories. However, pushing technique could be associated with adverse events. Also, during retrieval, with the conventional methods, the food bolus tends to fragment into small pieces making extraction both time and effort consuming. Cap-assisted endoscopic extraction of food bolus is an easier method. In this method, a cap is fixed to the tip of the scope and the bolus is removed by applying suction. However, data comparing it to other methods is scarce.

**Aims and Methods:** We aimed to compare two methods for extraction of an impacted esophageal food bolus; the cap-assisted suction method and the conventional methods. We retrospectively reviewed data from 253 patients who underwent endoscopy for food bolus extraction in the period between 2014 and 2017. We compared the two groups for the rate of en bloc removal, total procedure time, and procedure-related complications.

**Results:** 253 patients had endoscopy for food bolus extraction. In 76 patients (30%) the push-technique was used. 177 patients (70%) had one of the retrieval methods. The cap-assisted method was used in 84 patients while 93 patients had retrieval with the conventional methods. The application of cap-assisted technique achieved a higher rate of en bloc removal 82.1% compared to 11.8% with the conventional method (p < 0.001), a shorter procedure time (6.6 ± 3.2 minutes versus 15.3 ± 4.6 minutes, p < 0.0001), and less adverse events (0/84 versus 5/93, p = 0.01).

**Conclusion:** Cap-assisted removal of impacted esophageal food bolus is associated with more en bloc removal, shorter procedure duration, and less adverse effects compared to conventional methods. We encourage including this method in the options to remove an impacted esophageal food bolus.

Introduction:
Among 1280 patients with EGC, 663 patients were followed-up for over 5 years, in whom metachronous gastric neoplasm developed in 65 patients (10.0%). Rates of technical and clinical success were 100% rates of technical and clinical success. However, relapse of symptoms may occur in the mid term requiring additional treatment strategies. In the present study, we evaluated the correlation of the new technique of gastric poem (G-POEM). The question arises whether G-POEM may be a helpful tool for the treatment of gastric cancer after endoscopic resection discovered throughout previous studies.

Aims and Methods:
Patients with clinically and endoscopically and histopathologically diagnosis of gastric cancer by endoscopic resection were eligible for the study. Patients were randomized to G-POEM or BoTox injection with symptom relief thereafter. Finally, 34 patients were included in the G-POEM group, 32 patients in the BoTox group. G-POEM were performed with integrated injection function were used (Flush knife, Fujifilm; Dual Knife J, Olympus; Hybrid Knife, Erbe). All procedures were carried out under general anaesthesia using CO2 insufflation and periinterventional application of i.v. antibiotics.

Conclusion:
Metachronous gastric neoplasm had developed in 9.8% of patients with early gastric cancer (EGC) and the risk factors of metachronous tumor development in long-term follow-up.

Introduction: In contrast to POEM for achalasia, there is only limited data available on the new technique of gastric poem (G-POEM). The question arises whether G-POEM may be a helpful tool for the treatment of gastric cancer after endoscopic resection.

Aims and Methods: Patients with clinically, endoscopically and histopathologically confirmed diagnosis of gastric cancer after resection with pylorospasm and who had undergone repeated endoscopic resection sessions, e.g. by balloon dilation and/or BoTox injection with short-term relief were treated by G-POEM. ESD knives with integrated injection function were used (Flush knife, Fujifilm; Dual Knife J, Olympus; Hybrid Knife, Erbe). All procedures were carried out under general anaesthesia using CO2 insufflation and periinterventional application of i.v. antibiotics.

Conclusion: G-POEM was shown to be effective and safe in the short term with 100% rates of technical and clinical success. However, relapse of symptoms may occur in the mid term requiring additional treatment strategies.

Introduction: High-grade dysplasia or invasive cancer successful endoscopic mucosal resection (EMR) is recommended on the new technique of gastric poem (G-POEM). The question arises whether G-POEM may be a helpful tool for the treatment of gastric cancer after endoscopic resection.

Aims and Methods: This study included patients with FAP followed-up in our hospital. We excluded individuals with a history of upper gastrointestinal surgery. EGD was performed using FUSE by qualified endoscopists of the Japanese Gastroenterological Endoscopy Society and visibility of the ampulla of Vater was evaluated. The visibility of the ampulla of Vater was classified according to Woo et al., as follows: Type 1, the whole area of the papilla; Type 2, the upper part of the papilla including the orifice; Type 3, the upper part of the papilla excluding the orifice; Type 4, the lower part of the papilla including the orifice; or Type 5, no visualization of the papilla. The primary endpoint was the proportion of Type 1 in off-line review of the videos, and the secondary endpoint was that of Type 1 on in-site diagnosis.

Results: 49 FAP patients were enrolled in this study between July 2016 and December 2017. Patients were randomized to FUSE group (Type 1/ Type 2-4/ Type 5) or the conventional group (Type 1/ 2-4/ 5). In the FUSE group, the ampulla of Vater was visualized in 8/49 (16.3%) patients compared to 1/49 (2.0%) patients in the conventional group (p=0.012). Intrales correlation coefficients were 1.0 (FUSE group) and 0.85 (conventional group).

Conclusion: FUSE EGD is recommended for screening and surveillance endoscopy for patients with FAP.

Disclosure: Nothing to disclose

P0144 EFFICACY OF FULL-SPECTRUM ENDOSCOPY (FUSE) TO VISUALIZE THE AMPULLA OF VATER IN PATIENTS WITH FAMILIAL ADENOMATOUS POLYPOSIS (FAP): A PROSPECTIVE OBSERVATIONAL STUDY

Introduction: Duodenal cancer is one of the extracolonic malignancies which causes death in patients with familial adenomatous polyposis (FAP). However, the visualization of the ampulla of Vater is not always sufficient with standard esophagogastroduodenoscopy (EGD) because of a limited field of view. Full-spectrum endoscopy (FUSE) provides a wider 240° field of view with images on the front and left side of the lip of the endoscope. The aim of this prospective study was to evaluate the improvement of visualization of the ampulla of Vater in FAP using FUSE compared to standard EGD.

Aims and Methods: This study included patients with FAP followed-up in our hospital. We excluded individuals with a history of upper gastrointestinal surgery. EGD was performed using FUSE by qualified endoscopists of the Japanese Gastroenterological Endoscopy Society and visibility of the ampulla of Vater was evaluated. The visibility of the ampulla of Vater was classified according to Woo et al., as follows: Type 1, the whole area of the papilla; Type 2, the upper part of the papilla including the orifice; Type 3, the upper part of the papilla excluding the orifice; Type 4, the lower part of the papilla including the orifice; or Type 5, no visualization of the papilla. The primary endpoint was the proportion of Type 1 in off-line review of the videos, and the secondary endpoint was that of Type 1 on in-site diagnosis.

Results: 49 FAP patients were enrolled in this study between July 2016 and December 2017. Patients were randomized to FUSE group (Type 1/ Type 2-4/ Type 5) or the conventional group (Type 1/ 2-4/ 5). In the FUSE group, the ampulla of Vater was visualized in 8/49 (16.3%) patients compared to 1/49 (2.0%) patients in the conventional group (p=0.012). Intrales correlation coefficients were 1.0 (FUSE group) and 0.85 (conventional group).

Conclusion: FUSE EGD is recommended for screening and surveillance endoscopy for patients with FAP.

Introduction: The postoperative complications related to gastric conduit reconstruction after esophagectomy are still common issues after esophagectomy. We previously reported that the objective of the novel endoscopic scoring system which is significantly better in the FUSE group in both on-site diagnosis and off-line review (p<0.001). Intrales correlation coefficients were 1.0 (FUSE group) and 0.85 (conventional group).

Conclusion: FUSE EGD is recommended for screening and surveillance endoscopy for patients with FAP.

Disclosure: Nothing to disclose
Score 1: normal mucosa or erosion, score 2: less than 67% circumferential ischemic tissue formation, score 3: more than 67% circumferential ischemic mucosa or ulcer, or full-circumferential ischemic mucosa or ulcer formation with lesion length less than 20mm, score 4: full-circumferential ischemic mucosa or ulcer formation with lesion length more than 20mm. The highest score was then calculated for each patient.

The primary outcome measure was the predicting rate of the anastomotic complications using the scoring system within 2 months after esophagectomy. Clinical Trials.gov Registry, ID:NCT02973789.

Results: A total of 49 patients were enrolled in this study. 47 patients underwent esophagectomy to esophageal cancer. 2 patients underwent esophagectomy to benign strictures due to corrosive esophagitis and achalasia. 16 patients (33.3%) developed anastomotic complications after esophagectomy. Anastomotic leakage occurred in 4 patients. A stricture occurred in 13 patients. 1 patient had gastric conduit necrosis. All patients safely underwent endoscopic examinations without any complications. The incidence rates of each patients score 1, 2, 3, and 4 were 47.9%, 20.8%, 16.7%, and 14.6%, respectively. p < 0.05.

Next, the patients with a maximum score 3 or 4 were defined as the high-risk groups of anastomotic complications. The patients with maximum score 1 or 2 was defined as the low-risk groups of anastomotic complications. The sensitivity and the specificity of predicting the complications in high-risk groups were 62.5% and 100% at 1POD. The sensitivity and the specificity of predicting anastomotic complications in high-risk groups were 81.3% and 93.8% at 1POD.

Conclusion: Endoscopic examinations after esophagectomy were safely performed. The application of the endoscopic classification to mucosal ischemia after esophagectomy resulted in suboptimal accuracy to predict the anastomosis complications.

Introduction: Conventional surgery requires full-thickness suture in order to avoid leakage. Full-thickness suture has shown to be more effective than superficial suture, but full-thickness suture has been controversial in endoluminal surgery because it can cause external organs damage or bleeding. Partial-thickness suture has been attempted to ensure the stability, but its effect is questioned as the lack of support after endoluminal surgery. To evaluate the difference between both suture methods, it is necessary to consider widening the width when performing the partial-thickness suture to have similar strength. Further studies on endoscopic suture method in gastrointestinal tract are needed.

PI0147 AND WHEN NBI DOESN'T SHOW GASTRIC INTESTINAL METAPLASIA DO WE STILL NEED TO SEPARATE BIOPSY SAMPLES INTO DIFFERENT VIALS?

R. Castro1, G. Esposito2, M. Dinis-Ribeiro3, P. Pimentel Nunes1
1Instituto Português de Oncologia do Porto, Gastroenterology, Porto, Portugal
2Sant’Andrea - Università Sapienza, Digestive Endoscopy, Rome, Italy

Introduction: For the correct staging and classification of chronic atrophic gastritis (CAG) it is necessary to perform at least 4 biopsies (2 from the antrum/incisure and 2 from the body) with the biopsy samples being placed in different vials according to the current recommendations. Virtual Chromoendoscopy with Narrow-Band-Imaging (NBI) assists the diagnosis and vigilance of CAG.

Aims and Methods: We aimed to evaluate if, in the absence of a typical endoscopic pattern of GIM with NBI, biopsy samples can be placed in the same vial without implications in the diagnosis and follow-up of the patient. The aim of the prospective study was to perform an upper endoscopy with biopsies of both antrum/incisure and body. In every patient, upper endoscopy was performed with NBI. Patients with gastric lesions and/or suggestive areas of CAG were excluded. Patients included were submitted to ≥ 4 biopsies (2 from the antrum/incisure and 2 from the body) with the samples being placed in the same vial for histologic assessment (n = 182). Finally, histologic staging systems OLG and OLGIM were calculated.

Results: OLG and OLGIM calculation was possible for every patient. It was possible to distinguish samples from antrum/incisure from those of gastric body. In total, 178 (97.8%) presented OLGIM 0 and only 4 (2.2%) presented OLGIM 1. 149 (81.9%) presented OLG 0, 23 (12.6%) presented OLG1 and 5 (5.5%) presented OLG2. The placement of biopsy samples in the same vial had no implications in the diagnosis and follow-up in none of the patients since no one was diagnosed with severe gastric atrophy/intestinal metaplasia (negative predictive value of 100%).

Conclusion: In the absence of a typical endoscopic pattern of CAG with NBI, biopsy samples can be placed in the same vial if it is desired to determine the presence of Helicobacter pylori or even to abstain from biopsies if this is not the case. This change in clinical practice can have a significant financial impact on endoscopy costs.

Introduction: Helicobacter pylori (HP) eradication is an effective therapeutic approach to reduce gastric cancer mortality. In Japan, 1.5 million people annually undergo HP eradication; meanwhile, it has been revealed that despite successful eradication, the risk of gastric cancer persists for patients who already had precancerous lesions or progressed mucosal atypia. The aim of the present study was to create a novel computer aided endoscopic diagnosis (CAED) system for HP eradication history using linked color imaging (LCI) and deep learning (DL). CAED is a new image enhanced endoscopy (IEE) that enhances slight differences in mucosal color, while DL is a type of machine learning technology that imitates neural network in the brain.

Aims and Methods: The aim of this prospective study was to create a CAED system to distinguish between HP uninfected people and patients who have history of HP eradication therapy, using LCI and DL. In this study, we included patients who underwent EGD and were tested for serum HP antibodies (HPab) or urea breath test (UBT) at our medical clinic. Patients with active HP infection in the absence of eradication history, were excluded from the study. As a gold standard for HP infection status, we used HPab titer for uninfected subjects (≤ 5 U/ml, n = 148), and UBT value for eradicated patients (< 2.5%, n = 81). Patients underwent HP eradication out at our hospital. In total, 229 subjects were enrolled in this study. In order to evaluate the diagnostic accuracy of the CAED system patients were subdivided in 2 groups: a training group (n = 189, HP uninfected = 128, eradicated = 61); and a test group (n = 40, HP uninfected = 24, eradicated = 16). Comparing the output data from the test group with the actual data on HP infection status allowed us to assess the accuracy of the CAED system. During the course of the EGD an endoscopist took 3 LCI pictures of the lesser curvature, greater curvature, and antrum of the stomach using EG-L580NW (Fujifilm Co., Japan). The LCI images were subsequently augmented by rotation and right-left flip. We generated 2,508 training images and 480 testing images. An original DL model was designed, which has 18 deep convolutional layers for the CAED system. R (version 3.3.2) was used for statistical analyses.
Results: Area under the curve (AUC) of the receiver operating characteristics (ROC) for the lesser curvature, greater curvature, and antrum was 0.95 (95% CI 0.914–0.981), 0.93 (95% CI 0.882–0.969), and 0.89 (95% CI 0.843–0.944), respectively.

Conclusion: Patients with an HP infection are easy to diagnose without using EGD because noninvasive infection reaction is positive. In contrast, EGD is the only examination capable of distinguishing between HP-infected patients with low gastric cancer risk and patients with a history of eradication. The CAED system demonstrated excellent accuracy in distinguishing between the 2 groups using LGI. Our next step is to apply our findings to clinical practice.

Introduction: Delayed complications (bleeding or perforation) are major concerns of duodenal ESD. Recently, we conducted a retrospective study including about 170 cases of duodenal ESD and found both perforation and bleeding was much lower than those reported by previous reported (presented at DDW 2018). We have routine closed the post-ESD mucosal defect as far as possible, and we hypothesized the discrepancy of the outcomes between ours and previous studies was come from the difference in the proportion of complete closure of post ESD mucosal defect.

Aims and Methods: The aim of this study was to assess the efficacy of prophylactic closure of mucosal defect after ESD. This is a retrospective study from a university hospital. We collected the outcomes of duodenal ESD in 169 patients with duodenal epithelial neoplasia (174 lesions) treated by ESD at our department between July 2010 and January 2017. Study subjects were divided into 3 subgroups according to the degree of closure of post-ESD mucosal defect; complete group, incomplete group, and not attempted group. The proportion of delayed complications (including delayed bleeding and delayed perforation), the maximum serum level of C-reactive protein (CRP), and the total hospital stay were compared among these subgroups. Moreover, a multivariate logistic regression model to find risk factors for delayed complications.

Results: The proportion of delayed complications of patients in complete group, incomplete group and not attempted group were 1.7%, 23% and 15.6%, respectively. The difference between complete group and the others was significant (p < 0.01). Maximum serum CRP level was much lower in complete group (1.51 ± 2.18 vs. 6.28 ± 10.0 mg/dl, p < 0.01) and hospital stay was significantly shorter in complete group than in incomplete/none group (median [range] 4 [4–13] vs. 7 [3–58] days, p < 0.01). Multivariate analysis revealed complete closure was an only independent predictor to reduce delayed complications and it revealed about 95% significant decrease of delayed complications.

Conclusion: The present study revealed that complete closure of the mucosal defect after duodenal ESD significantly decreased delayed complications and improved other outcomes such as inflammatory reaction or duration of hospital stay.

Introduction: Familial adenomatous polyposis (FAP) is an inherited autosomal-dominant disease characterized by the development of polyps both in the upper and lower gastrointestinal tract. With the implementation of prophylactic colectomy, the incidence of colorectal cancer has declined and extracolonic manifestations have become more relevant.

In what gastric lesions are concerned, FAP patients are known to have an increased risk for gastric dysplasia, although it is unclear if these lesions confer an increased risk of gastric cancer.

Aims and Methods: The aim of our study was to characterize gastric dysplastic lesions in patients with FAP. We enrolled 144 patients with germline mutation in the APC gene from 63 FAP families and we retrospectively reviewed 366 Upper Gastrointestinal Endoscopies (UGE) performed during regular surveillance at the Familial Cancer Clinic.

Statistical tests: Chi-square, Fisher’s Exact Test, Student T test, Mann-Whitney U test, Cox Regression Model

Results: From the 144 patients included in the study, 94 (Men: 49 Women: 45, mean age 48.3 ± 14.8 years) underwent UGE at least once during a median follow-up period of 12.7 ± 5.7 years. The dysplastic lesions were detected in 16 patients (17%) at 37 endoscopically visible lesions (Paris classification: 0-Ip: 10, 0-IIa: 7, 0-IIa+C0: 10, 0-IIc: 10). The proportion of delayed complications (including delayed bleeding and delayed perforation), the maximum serum level of C-reactive protein (CRP), and the total hospital stay were compared among these subgroups. Moreover, a multivariate logistic regression model to find risk factors for delayed complications.

Conclusion: The present study revealed that complete closure of the mucosal defect after duodenal ESD significantly decreased delayed complications and improved other outcomes such as inflammatory reaction or duration of hospital stay.

PO150 COMPARISON BETWEEN ENDOSCOPIC SUBMUCOSAL DISSECTION AND SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION FOR ESOPHAGEAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA LAYER
J. Zhu1, Q. Li1, T. Chen1, P. Zhou1
1Zhongshan Hospital, Fudan University, Endoscopy Center, Shanghai, China
Contact E-Mail Address: zjyjst@yahoo.com

Introduction: Endoscopic submucosal dissection (ESD) or submucosal tunneling endoscopic resection (STER) is widely acknowledged as an important treatment option for esophageal submucosal tumors from the muscularis propria layer. However, the clinical outcomes of ESD or STER for esophageal submucosal tumor have not been completely evaluated.

Aims and Methods: The aim of this study is to compare the 2 different treatments. We retrospectively collected the data of 876 patients who had undergone ESD or STER for esophageal submucosal tumors from January 2011 to September 2015 in the Endoscopy Center of Zhongshan Hospital. Gender, age, tumor size, depth and shape, procedure time, complications, postoperative length of stay, and follow-up duration between ESD and STER groups were compared.

Results: 424 patients received ESD, while 452 patients received STER. There was no significant differences in age, gender, tumor size, depth and shape, or procedure time, complications, postoperative length of stay, and follow-up duration between ESD and STER groups. Moreover, the patients receiving STER had a longer procedure time due to closing the tunnel entrance (ESD vs STER, 23.2 ± 16.5 min vs. 44.0 ± 25.8 min, p < 0.001). No recurrence and death was occurred in the STER and ESD groups during a mean follow-up of 50.0 and 51.8 months, respectively.

Conclusion: Both ESD and STER would likely be effective and safe alternatives for resecting SMTs < 10mm. Accounting for safety and preventing perforation, we are inclined to STER for SMTs > 10mm. Additionally, the choice between the 2 procedures would also depend on the depth and shape of submucosal tumors.

Disclosure: Nothing to disclose
Histopathologic findings revealed 28 lesions with low-grade dysplasia (LGD), 8 with high-grade dysplasia (HGD) and 2 adenocarcinomas, both diagnosed in the first UGE performed. In regard to the evolution of dysplasia, 7 patients maintained LGD in the subsequent EGDS; only one patient had progression from LGD to HGD, in a 1 year period. This case involved multifocal dysplasia of the antrum and the patient underwent subtotal gastrectomy. The majority (70.3%) of gastric dysplastic lesions were treated endoscopically (endoscopic mucosal resection: 16; polypectomy: 9; endoscopic submucosal dissection: 1) and surgery was conducted in 2 cases.

Gastric dysplasia was positively associated with the presence of gastric polyps and flat lesions (p = 0.014 and < 0.001, respectively) and with atrophic gastritis and/or intestinal metaplasia (p = 0.001). Gastric dysplasia was not associated with FAP phenotype, Helicobacter pylori infection or the presence/number of FGP.

Conclusion: Despite the high prevalence of gastric dysplasia in FAP patients, its course is indolent. This may allow endoscopic surveillance and validate a conservative treatment strategy in the majority of cases.

Introduction: The endoscopic approach of esophageal perforations poses a therapeutic challenge. Recently, a predictive score has been proposed to predict the chance of endoscopic stenting in patients with esophageal leaks. This score consists of 4 clinical variables that proved to be effective in discriminating the probability of success, especially when the probability of success is >70% or ≤50%, with lower discriminatory power in case of intermediate probabilities (50-70%).

Aims and Methods: We aimed to evaluate the applicability of the clinical score in a cohort of patients with anastomotic leaks managed with fully/partially covered stents in FAP.

Conclusion: The application of this predictive model proves to be useful in clinical practice, favoring management with endoscopic stenting in patients with probability of success ≥50%. It is cautious to consider other therapeutic options in patients with a lower probability of success.

Introduction: Implementation of colorectal cancer (CRC) screening programs and the improvement of endoscopic techniques increases the endoscopic resection of polyps with early invasive CRC (pT1 Nx M0). The risk of lymph-node metastasis often leads to additional surgery, but despite guidelines, correct management remains unclear.

Aims and Methods: Aim of this study was to assess factors affecting the decision-making process in endoscopically resected pT1-CRCs in an academic centre. We retrospectively reviewed patients undergoing endoscopic resection of pT1-CRC from 2006 to 2016. Clinical, endoscopic, surgical treatment and follow up data were collected and analysed. Such lesions were categorized according to endoscopic/histological risk-factors in low- and high-risk groups. In detail, low-medium grade of differentiation, no lymphovascular invasion, no tumour budding, Haggi 1-3 and Kikuchi sm1, and en bloc resection was considered as low-risk pT1-CRC. Comorbidities were classified according to Charlson index (CCI). Surgical referral for each group was computed, and dissociation from current European CRC screening guidelines recorded. Multivariate analysis for factors affecting the post-endoscopic surgery referral was performed.

Results: 72 patients with endoscopically resected pT1-CRC were included. Overall, 20 (27.7%) and 52 (72.3%) were classified as low- and high-risk, respectively. In the low-risk group, 11 (55%) were referred to surgery, representing an over-treatment as compared with current guidelines. In the high-risk group, a non-surgical endoscopic surveillance was performed in 20 (38.5%) cases, representing a potential under-treatment. After median follow up of 30 (6-130) months, no patients developed tumour recurrence. At multivariate analysis, age (OR 1.21; 95% CI 1.02-1.42; p = 0.02) and co-morbidities (CCI ≥ 1.67, 95% CI 1.12-3.14; p = 0.04) were independent predictors for subsequent surgery.

Conclusion: A substantial rate of inappropriate post-endoscopic treatment of pT1-CRC was observed, when compared with current guidelines. This was apparently related with an over-estimation of patient-related factors rather than endoscopically or histological-related factors.

Disclosure: Nothing to disclose

P0155 PINE-CONE AND VILLI PATTERNS ARE ENDOSCOPIC SIGNS SUGGESTIVE OF ULCERATIVE COLITIS-ASSOCIATED COLORECTAL CANCER AND DYSPLASIA

Contact E-Mail Address: takahide124@gmail.com

Introduction: Patients with ulcerative colitis (UC) are at high risk for the development of colorectal neoplasia: colitis-associated cancer or dysplasia. We recently performed a randomized controlled trial comparing targeted vs. random biopsy and demonstrated that targeted biopsies were almost comparable to random biopsies in terms of the neoplasia detection rate when performed by experienced colonoscopists; however, the appropriate site for targeted biopsy is still unclear. Therefore, endoscopic findings of neoplastic lesions for targeted biopsy are necessary for the further effective surveillance colonooscopy.

Aims and Methods: We aimed to elucidate key endoscopic findings suggestive of colitis-associated cancer or dysplasia. We retrospectively evaluated patients with UC-associated neoplasia. Surgical procedures were performed between April 2016 and October 2017 at a single referral centre (Department of Surgical Oncology, the University of Tokyo, Japan). Two gastrointetinal (GI) surgeons/endoscopists, who were blinded to the pathological diagnosis, independently assessed the images and classified them according to Kudo’s pit pattern and surface morphology, such as pine-cone/villi patterns. GI pathologists independently made pathological findings. The correlation between stereoscopic and pathological findings (neoplastic vs. non-neoplastic) for each image was investigated. The interobserver agreement was assessed using kappa statistics.

Results: Kudo’s neoplastic pit patterns (type III-V) were significantly correlated with the presence of neoplasia (sensitivity 77.4%, specificity 89.5%, positive
predictive value 92.8%), with a substantial concordance rate (kappa value 0.677). A hundred regions presented with pine-cone/villi patterns, which showed high specificity (96.8%) and positive predictive value (92.0%) for neoplasia, although sensitivity was low (21.4%). Concordance rate was also substantial (kappa value 0.625). A revision of the endoscopic findings of flat dysplasia with non-neoplastic pit patterns (9 lesions in 6 patients) revealed that 7 of 9 lesions had a reddish area with a demarcation line in each neoplastic lesion.

Conclusion: Targeted biopsies in surveillance colonoscopy for patients with UC must focus on lesions showing pine-cone/villi patterns in addition to Kudo’s non-neoplastic pit patterns such as type III, IV or V. For some flat neoplastic lesions with non-neoplastic pit patterns such as type I or II, a reddish area with a demarcation line may be one of the effective clues for targeted biopsy.

Contact E-Mail Address: alessandro.repici@humanitas.it

Introduction: High-quality colon cleansing is associated with improved lesion detection during colonoscopy (1-3). The cleansing efficacy and safety of NER1006, a novel 1L polyethylene glycol (PEG)-based bowel preparation, was evaluated in 3 randomised phase 3 trials DAYB1, MORA2, and NOCT3.

Aims and Methods: For each trial, this post hoc analysis compared the level of high-quality, segmental cleansing attained by NER1006 versus its comparator: Sodium Polysulfate + Mg Citrate (SPMC; DAYB), 2L PEG + Ascorbate (2LPEG; MORA) and Oral Sulfate Solution (OSS; NOCT). Dosing regimens varied by trial. All trials used treatment-blinded central reader-assessed cleansing scores and similar recruitment criteria. Alternative primary endpoints were overall and right colon cleansing using the validated Harefield Cleansing Scale (HCS). The number and share of high-quality segments (HCS score 3-4) assessed by a 3-image comparator were analysed in 3 primary analysis populations: The full analysis set (FAS; all randomised patients), the modified FAS (mFAS; FAS excluding any patient who failed lab screening after randomisation and who also did not take their study treatment), and the Per-protocol set (PP; FAS with fulfilled entry criteria, who took ≥75% of both study preparations doses, had data for at least 1 of the primary endpoints, and no major protocol deviations).

Results: A total of 1,985 patients were included in this analysis (Table 1). In each of the 3 primary analysis populations (FAS, mFAS, PP), day before dosing with NER1006 attained significantly more high-quality segments than with SPMC (16.9% vs. 10.4%, p < 0.001, 17.4% vs. 10.7%, p < 0.001, 18.4% vs. 10.7%, p < 0.001). Overnight split dosing with NER1006 showed more high-quality segments than with 2LPEG (46.1% vs. 29.0%, p < 0.001, 47.5% vs. 30.2%, p < 0.001, 48.7% vs. 32.5%, p < 0.001). Morning only dosing with NER1006 in AM also achieved more high-quality segments than overnight split dosing with 2LPEG PM/AM (46.8% vs. 29.0%, p < 0.001, 48.1% vs. 30.2%, p < 0.001, 50.6% vs. 32.5%, p < 0.001). Finally, overnight split dosing with NER1006 PM/AM delivered more high-quality segments than with OSS (40.1% vs. 36.2%, p = 0.013, 45.0% vs. 40.2%, p = 0.005). No serious adverse events were reported in the entire population in this post hoc pooled analysis.

Introduction: Colorectal cancer is the second most commonly diagnosed cancer in Ireland. (1) Complete polypectomy is common among Endoscopists(2) NCCLS (National Colon Cancer Screening) colonoscopies are offered to bowel cancer screening patients after a positive Faecal Immunochromatographic Testing (FIT). These anecdotally have larger polyps. The goal of polypctomy is to achieve an R0 margin meaning that the margin is free of abnormal tissue.

Aims and Methods: To determine whether there is an association of R0 resection margin with Endoscopist, histopathologist, size, location and technique of polypectomy in an NCCS cohort. It was a retrospective observational study on 3 primary analyses between October 2013 and June 2017. These procedures were conducted in a single centre at Louth county hospital (LCH). SPSS software was used for statistical analysis. Statistical significance was set a priori at 0.05.

Results: In this ongoing study a total 542 colonoscopies were performed with no polyps in 19%. Here we present a subanalysis of 186 colonoscopies on which 707 polyps were identified. The average age was 66 years (SD 2.8) with 190 (27%) females. The polyp distribution was 255 (36%), 85(12%) and 365 (52%) in right, transverse and left colon respectively. Most of the polyps were less than 5 mm (59%) with 11.5% more than a cm in size. 152 (22%) had an R0 margin histologically, and 30 (5%) had involvement of the margin. In 373 (67%) polyps histopathologist were unable to assess the margin and (33%) polyps were not retrieved. Polypectomy technique in the form of hot snare had a direct relation with R0
Our study is the largest study comparing UEMR with conventional EMR. Accessibility of margins also had a linear relation with the size of the polyp, resection technique, statistically significant difference between hot snare and biopsy to cold biopsy and snare (p<0.02) and the reporting pathologist. Achieving an R0 margin was not statistically significant with endoscopic (experienced endoscopist on average do more than 300 colonic polyps per year), size and location of the polyp.

Conclusion: Only 25% of the polyps retrieved achieved an R0 margin while in 71% cases pathologist were unable to assess the margin. A multidisciplinary approach has to be developed between the endoscopist and pathologist achieving R0 margin. Polypometry requires significant focused training and experience to maximize success. In future, this could be included as a key performance indicator for polypectomy. We also recommend more studies on margin analysis.

P0161 COMPARING THE EFFICACY AND SAFETY BETWEEN UNDERWATER ENDOSCOPIC MUCOSAL RESECTION AND CONVENTIONAL ENDOSCOPIC MUCOSAL RESECTION IN RESECTING SESSILE COLORECTAL NEOPLASMS: A PROPENSITY SCORE-MATCHED COHORT STUDY

P. Kishchuk,
1Chimei Medical Center, Department of Gastroenterology, Tainan, Taiwan
2Fujien Catholic University Hospital, Department of Gastroenterology, New Taipei City, Taiwan
3University of Arizona, College of Phamacy, Tucson, United States

Contact E-Mail Address: pb6401099@gmail.com

Introduction: Colonoscopy resection of colorectal polyps has been shown to reduce colorectal cancer related death.1 For sessile colorectal polyps, endoscopic mucosal resection (EMR) is an established method for the removal of.2 However, recurrence after EMR is a major limitation. Piecemeal resection and intraprocedural bleeding are reported to be risk factors of recurrence after EMR.3,4 Underwater EMR (UEMR) was proposed as an alternative method for removal of colorectal polyps.5 There is no large-scale dataset directly comparing the efficacy and safety of UEMR with conventional EMR in resecting average sized lesions.

Aim of Study: The aim of our study is to compare efficacy and safety of UEMR with conventional EMR in average sized colorectal sessile polyps using a large retrospective cohort with propensity score matched design.

A retrospective observational study was conducted on all adult patients referred to us for endoscopic resection of sessile colorectal polyps between August 2012 and November 2017. During this period, conventional EMR was performed until August 2015, when UEMR was introduced to our hospital, and UEMR was performed for all lesions after August 2015. Follow-up of the patients was by a clinic visit around 7–14 days after the procedure to monitor adverse events. Surveillance colonoscopy was scheduled according to MSTF guidelines. The outcome measures included en bloc resection rate, procedure time, bleeding, and margin status. We match and control the baseline differences of both groups in a 1:1 ratio by calculating propensity scores using a multivariable regression model.

Results: 462 lesions in 407 consecutive patients were treated. In the first study period between August 2012 and August 2015, all of the 256 lesions in 222 patients were resected by conventional EMR. In the second study period between August 2015 and November 2017, all of the 206 lesions in 183 patients were resected by underwater EMR.

- The propensity score matching created 170 matched pairs (totally 340 patients).
- The mean age was 64 years old.
- With highest ADR in the 6 months immediately after intervention.
- The Sydney EMR recurrence tool.

Conclusion: The aim of this study is to compare individual ADR before and after intervention, and determine factors associated with response in a multi-centre study in Singapore. We also recommend more studies on margin analysis.

Disclosure: Nothing to disclose.

Introduction: Adenoma detection rate (ADR) is a key indicator of colonscopy quality. Previous studies have shown that performance feedback can improve ADR, but these were mostly based in the West and lack examination of factors associated with response.

Aims and Methods: The aim of this study is to compare individual ADR before and after intervention, and determine factors associated with response in a multi-centre study in Singapore. We also recommend more studies on margin analysis.

Aim of Study: The aim of this study is to compare individual ADR before and after intervention, and determine factors associated with response in a multi-centre study in Singapore. We also recommend more studies on margin analysis.

Results: 33 endoscopists who performed 21,760 scopes met the inclusion criteria. Overall adjusted baseline ADR was 27.3%(±1.3%) and increased to 31.8%(±0.9%) after intervention (p<0.01). At baseline, 12 endoscopists had ADR < 25%. Their ADR increased from 17.0%(±2.0%) to 27.3%(±1.3%) after intervention (p<0.01), with highest ADR in the 6 months immediately after intervention. APC, proximal ADR, proportion of cases with large poly<5mm also increased after intervention (0.25 to 0.50, 8.8% to 16.3%, 14.7% to 22.8% respectively, all p<0.01). 6 responders and 6 non-responders were identified. Responders had higher mean patient age (66.6 vs. 56.3 years), performed more scopes with BBPS>5 (94.9% vs. 92.0%, p<0.01) and more screening scopes (33.4% vs. 25.3%, p<0.01) than non-responders. Non-responders had shorter WT, but this difference was not significant after intervention (0.01). 5(94.9%) responders had higher quality scores in ADR after intervention.

Conclusion: Quality scorecards were successful in improving ADR in a multi-centre study in Asia. Response to feedback is multi-factorial. Increased WT alone without improving other modifiable factors may not result in improved ADR after feedback.

Disclosure: Nothing to disclose.

Introduction: Narrow-band imaging (NBI) magnifying endoscopy has been reported to be useful for qualitative and quantitative diagnosis of colorectal lesions. Recently, Japan NBI Expert Team (JNET) classification was advocated which is the first universal narrow-band imaging magnifying endoscopic classification for colorectal tumors. The method, magnifying endoscopy requires high experience and skill. On the other hand, dual-focus NBI with electronic zoom (DF-NBI) can easily provide almost the same image of optical zoom magnifying images only by button push.

Aims and Methods: The aim of study is to clarify the usefulness of JNET classification with DF-NBI for colorectal tumors. We analyzed consecutive 290 colorectal lesions, which were diagnosed by JNET classification with DF-NBI observation before endoscopic treatment or surgery between April 2017 and
March 2018. The instrument used in this study was a dual focus endoscope (CF- HD160, Olympus). The lesions were diagnosed in accordance with the criteria of the World Health Organization. Using these cases, we examined the relationship between each type of the JNET classification with DF-NBI and histopathological findings. We calculated sensitivity, specificity, positive and negative predictive value (PPV and NPV), and accuracy for each category of the classification. The JNET classification; the colorectal NBI magnifying classification consists of 4 types that are classified based on vessel pattern and surface pattern. The characteristics of Type 1 are invisible vessel pattern and having regular dark or white spots as surface pattern. The characteristics of Type 2A are regular vessel pattern. Polyp size over 25mm was a risk factor of intra-procedural bleeding (p=0.015). Polyp size over 25mm was a risk factor of intra-procedural bleeding after EMR without detachable snare.

**Conclusion:** 1:20000 epinephrine injection should be performed for over 25mm colon polyp to prevent intra-procedural bleeding after EMR without detachable snare.

**Contact E-Mail Address:** fares.ayoub@medicine.ufl.edu

**Introduction:** The main aim of this study was to conduct a meta-analysis on the effect of clipping on DPB following endoscopic mucosal resection (EMR) of colorectal lesions ≥ 20 mm.

**Aims and Methods:** The main aim of this study was to conduct a meta-analysis on the effect of clipping on DPB following endoscopic mucosal resection (EMR) of colorectal lesions ≥ 20 mm. We performed a search of PubMed and the Cochrane library for studies comparing the effect of clipping vs. no clipping on DPB following endoscopic resection. The Cochran Q test and I2 were used to test heterogeneity. Pooling was conducted using a random-effects model.

**Results:** 13 studies with a total of 7794 polyps were included. Overall, when lesions of all sizes and types of endoscopic resection (conventional polypectomy, EMR or endoscopic submucosal dissection [ESD]) were included, DPB was observed less frequently with clipping (1.3%) as compared to no clipping (2.7%) (pooled OR 0.50, 95% CI: 0.25–0.91, p=0.02). In the subgroup analyses, clipping was also associated with a decrease in the rate of DPB after (1) resection of lesions ≥20 mm (pooled OR: 0.33; 95% CI: 0.18–0.62; p=0.001) and for lesions <20 mm removed by EMR (pooled OR 0.24, 95% CI: 0.12–0.50, p<0.001).

**Conclusion:** Prophylactic clipping may reduce DPB following EMR of large colorectal lesions. Future trials are needed to further identify risk factors and stratify high risk cases in order to implement a cost-effective preventive strategy.

**Disclosure:** Nothing to disclose
significant difference in age, sex, current medication, reason for colonoscopy, colonoscopic findings and polyp detection rate between the 2 groups. Constipation and past history of abdominal surgery was found to be predictive of a failed repeated preparation (Odd ratio = 1.54, 95% CI (1.14-2.07), p = 0.004).

Conclusion: Second colonoscopy on next day with NaP 45 mL was more effective than after 7 days with PEG 4L in colonic preparation failure. Constipation and past history of abdominal surgery were significant risk factors of repeated preparation failure.

Disclosure: Nothing to disclose.

P0167 1L NER1006 ACHIEVES HIGH-QUALITY BOWEL CLEANSING WITH LOWER TOTAL FLUID VOLUME INTAKE THAN STANDARD POLYETHYLENE GLYCOL + ASCORBATE: A POST-HOC ANALYSIS

Introduction: Successful bowel cleansing is required for effective colonoscopy. Polyethylene glycol (PEG)-based bowel preparations are widely used for this, despite many still requiring high fluid volume intake. To enhance the patient experience, the phase 2 study OPT2 assessed the clinical proof of concept of NER1006, a novel 1L PEG-based bowel preparation, versus standard 2L PEG + ascorbate (2LPEG). Here we report the cumulative segmental cleansing score versus total fluid intake for NER1006 and the Control.

Aims and Methods: The OPT2 study had 2 parts and evaluated 5 different low volume PEGs vs the control. This post-hoc analysis assessed the lead phase 3 candidate, NER1006, from Part 2 of the study vs the Control. Treatment-blinded colonoscopists assessed the bowel cleansing quality using the Harefield Cleansing Scale (HCS). For each patient, the sum of observed segmental cleansing scores (0-4) for each of the 5 segments (cumulative maximum total = 20), and the total fluid volume intake (i.e. preparation volume + mandatory additional clear fluid volume + voluntary ad libitum clear fluid volume) were assessed. The number and share of patients who attained high-quality cleansing (segmental HCS scores 3 or 4) in all segments (cumulative HCS score of 15 or higher) were calculated.

Results: 60 patients underwent screening colonoscopy (Table 1). They were either 40 to 70 years old with a known personal or familial risk of contracting colorectal cancer, or 55 to 70 years old. 30 patients per group had their bowels prepared within less than 5mm in diameter, that was 10.4%, 0% and 0%, respectively. Most of the flat-type (91.9%) and protruded-type (94.3%) lesion showed type III or IV pit pattern corresponding to adenomas, whereas 91.7% of the depressed-type lesions were characterized by type III, VI or VN pit patterns corresponding to carcinomas. For endoscopists, most of the flat- and protruded-type lesions showed EC2 corresponding to adenomas. In contrast, the depressed-type lesions were observed as EC3 (59.0%) and EC3b (53.5%) corresponding to invasive carcinomas.

Conclusion: This study revealed the diagnostic characteristics of depressed-type lesions. They show typically type III, VI or VN pit patterns in magnifying endoscopy and type EC3a or EC3b in endoscopy. These lesions tend to invade the submucosal layer even when they are small. It is important to diagnose colorectal neoplasms according to their morphology.

Disclosure: Nothing to disclose.

P0169 ENDOCYTOSCOPY FEATURE OF DEPRESSED TYPE COLORECTAL NEOPLASMS IN MAGNIFYING ENDOSCOPY AND ENDOCYTOSCOPY

Shosha University Northern Yokohama Hospital Digestive Disease Center, Yokohama, Japan

Contact E-Mail Address: kudos@med.shosha-u.ac.jp

Introduction: Colorectal cancers are generally recognized to develop from polyps. This adenoma-carcinoma sequence theory has been in the mainstream of development of colorectal cancers. However, recently the existence of many depressed-type lesions has been revealed, which are considered to emerge directly from normal epithelium, not through the adenomatous stage. This theory is called de novo pathway.

Now, it is possible to presume the histology of colorectal lesions using magnifying endoscopy (pit pattern classification) and endocytoscopy (EC classification). We can observe not only the structural atypia but also the cellular atypia in vivo.

Aims and Methods: The aim is to clarify the endoscopic characteristics of depressed-type colorectal neoplasms, demonstrating the validity of pit pattern and EC classification.

A total of 30021 colorectal neoplasms excluding advanced cancers were resected endoscopically or surgically in our unit from April 2001 to May 2017. Of these, 22958 lesions were low-grade dysplasia, 5913 were high-grade dysplasia and 1150 were submucosally invasive (T1) carcinomas. According to the developmental morphology classification, they were divided into 3 types: depressed, flat and protruded-type. We investigated the rate of T1 carcinomas and the characteristics of depressed-type neoplasms concerning pit pattern and EC classification.

Results: The rate of T1 carcinomas in depressed-type lesions reached to 62.1%, meanwhile that in flat-type and protruded-type lesions was 3.4% and 2.9%, respectively. Within less than 3mm in diameter, that was 10.4%, 0% and 0%, respectively. Most of the flat-type (91.9%) and protruded-type (94.3%) lesion showed type III or IV pit pattern corresponding to adenomas, whereas 91.7% of the depressed-type lesions were characterized by type IIIS, VI or VN pit patterns corresponding to carcinomas. For endoscopists, most of the flat- and protruded-type lesions showed EC2 corresponding to adenomas. In contrast, the depressed-type lesions were observed as EC3a (59.0%) and EC3b (53.5%) corresponding to invasive carcinomas.

Conclusion: This study revealed the diagnostic characteristics of depressed-type lesions. They show typically type III, VI or VN pit patterns in magnifying endoscopy and type EC3a or EC3b in endocytoscopy. These lesions tend to invade the submucosal layer even when they are small. It is important to diagnose colorectal neoplasms according to their morphology.

**Contact E-Mail Address:** yoshimurat2017@gmail.com

**Introduction:** In the ESGE and Japanese guidelines, perioperative heparin bridging is recommended for high thrombotic risk patients who are receiving anticoagulation before endoscopic procedures. We retrospectively investigated clinical outcomes of patients with atrial fibrillation who had been applied perioperative bridging anticoagulation by intravenous unfractionated heparin for high-risk endoscopic procedures at our institution between April 2006 to June 2017.

**Aims and Methods:** We retrospectively investigated clinical outcomes of patients with atrial fibrillation who had been applied perioperative bridging anticoagulation by intravenous unfractionated heparin for high-risk endoscopic procedures at our institution between April 2006 to June 2017. (1) Warfarin was discontinued 5 days before the procedure and intravenous unfractionated heparin was started with 5000 unit bolus followed by 500 unit per kilogram of body weight per day continuous intravenous injection. (2) Activated partial thromboplastin time (APTT) was evaluated to adjust the dose of heparin to raise APPT to 45 to 70 seconds. (3) Heparin was discontinued 4-6 hours before the endoscopic procedure and resumed from the next morning. (4) Warfarin was also resumed along with heparin with a loading dose of 5mg for 3 days followed by a preoperative dose of the patient. (5) Heparin was discontinued when INR reached 1.6 or higher. The primary outcomes were arterial thromboembolic events within 30 days of the endoscopic procedures, and postoperative bleeding events that needed endoscopic hemostasis or blood transfusions were treated as complications. Results: During the study period, 76 cases received high-risk endoscopic procedures among them, 2 cases refused heparin bridging, thus we assessed 74 (19 females) cases with a mean age of 73.8 years old in the study. The endoscopic procedures were colorectal EMR or ESD (29 cases), gastric ESD (23 cases), colorectal sphincterotomy (15 cases), esophageal ESD (15 cases), and duodenal EMD (2 cases). There was no arterial thromboembolic event within 30 days of the endoscopic procedures, and postoperative bleeding events that needed endoscopic hemostasis or blood transfusions were treated as complications. Discussion: Nothing to disclose

This post hoc analysis assessed the duration of the cleansing efficacy so treatments with sustained high efficacy would be valuable.4

High-quality bowel cleansing facilitates effective colonoscopy.1–3

Aims and Methods: Patients aged 18–85 years were randomized to receive a split-dosing regimen of either evening/ morning (PM/AM) NER1006, or 2LPEG or OSS. Overnight split dosing started at ~6:00 pm (± 2 h) with dose 2 at ~6:00 am (± 2 h). The percentage of patients with overall bowel cleansing success (Harefield Cleansing Scale grades A and B) was analysed by duration between the end of the second dose of the bowel prep plus mandatory fluids and the start of colonoscopy (1-h intervals: ≤ 3, > 3–4, > 4–5, > 5–6, > 6–7, or > 7 h). Data were analysed in the modified full analysis set (mFAS) population, which comprised all patients who received at least 1 dose of study drug and who had documented primary colonoscopy data from a central reader. Patients included in the analysis of variance (ANOVA) between time intervals and colon cleansing success also needed calculable time intervals after dose 2.

Results: Data from 1037 patients were included in the analysis (Table 1). In time intervals from up to 3 h to over 7 h after dose 2, successful bowel cleansing was attained in at least 88% (7 out of 8) patients with NER1006 PM/AM regimen. At >7 hours NER1006 PM/AM attained at least 89.3% HCS cleansing success whereas this level of cleansing efficacy was not attained by either 2LPEG or by OSS (p < 0.001). Data showed reduced success rates after 7 hours (81.3% and 77.4%, respectively). The ANOVA revealed a significant decline in efficacy over time for OSS (p = 0.033). No such differences were observed for NER1006 PM/AM (p = 0.32, MORA, p = 0.36, NOCT) or 2LPEG (p = 0.15).

Conclusion: Split dosing with NER1006 evening morning dosing can, in a reproducible fashion, deliver overall cleansing success in 7 out of 8 patients even after 7 or more hours post dose 2. This sustained efficacy may become particularly useful for afternoon or delayed colonoscopies.

Introduction: Computer-aided diagnosis (CAD) for colonscopy is drawing attention as an attractive tool to identify neoplastic polyps requiring resection from non-neoplastic polyps that can be left in situ [1]. However, its role has not been established because of the lack of high-quality clinical trials.

Aims and Methods: We aimed to clarify the efficacy of “real-time” use of CAD with 500-fold ultra-magnifying endoscopes [2] with a single arm, open-label, prospective trial. This trial included 821 patients undergoing colonoscopy with use of CAD in a tertiary university hospital between June and December 2017. CAD predicted pathology (neoplastic or non-neoplastic) of the diagnosis of diminutive polyps (≤5 mm) based on real-time outputs. CAD performance was evaluated, with the actual pathology of the resected specimen as the gold standard. The CAD system had been trained with 61925 endoscopic images acquired from a total of 5 universities hospitals and cancer center hospitals in Japan, where we established the diagnostic strategy of using CAD in the field. The primary aim of this study was to assess the cost and benefits of endoscopic submucosal dissection. The secondary aims of the study are to assess the part of sterile medical devices (SMD) in the overall cost of the procedure, to determine predictive factors for a positive cost/benefit balance and to do a medicoeconomic comparative with surgery for superficial colonic neoplasms.

Results: Overall, 466 diminutive polyps (including 250 in the rectosigmoid colon) from 325 patients were assessed by CAD using both the narrow-band imaging (NBI) mode and the methylene blue-stained mode. CAD was able to analyze 95.1% (457/486) of the polyps. Intention-to-treat analysis, in which non-analyzable polyps were treated as misdiagnosed ones, revealed mean NPsVs for CAD regarding diminutive, rectosigmoid polyps of 95.2% (95% confidence interval, 90.3–98.0) for the NBI mode and 93.7% (88.3–97.1) with the stained mode. The diagnostic sensitivity, specificity, and accuracy of CAD were as follows; 83% (95% confidence interval, 64%–94%), 97% (94%–99%), and 93% (89%–96%) in the segment-based analysis, 77% (64%–87%), 97% (94%–99%), and 93% (89%–96%) in the patient-based analysis, respectively. The difference between the overall cost and the revenue provide the medicoeconomic study with core information. We have selected in the same center patients who had surgery from 2009 to 2017 for superficial colonic neoplasms in our hospital. After the etiologic factor analysis by Stepwise logistic regression analyses, the predictive factor for a positive budgetary balance which was a severity level of DRG higher than 1 (OR 9.91; IC95% 11.3–214.25; p < 0.0001). We compared colonic surgery and ESD for superficial lesions in the same center/hospital. 69 patients were in surgery and 71 in ESD. There is no significant difference between the 2 groups in terms of age, localization, anatomopathology or ASA score. The size of lesions was twice higher in ESD than in surgery (50 mm vs. 25 mm; p < 0.0001). The average length of hospitalization was superior in surgery (11 days vs. 2 days in ESD; p < 0.0001). Morbidity at 30 days was not significantly superior in surgery (28 vs. 14% in ESD; 0.061). At country level, the cost of surgery was 5 times higher if we consider revenue related to the stay (€8,960 vs. €1,770; p < 0.0001). But at the hospital scale, the budgetary balance was positive for surgery patients (€2,400 vs. -€8,800 in the dissipation of cost).

Conclusion: As of today, the ESD benefit/deficit balance is negative in 80% of cases. Overcharge is due to a lack of act ranking. Specific dissection equipment accounts for the largest share of expenditures. It is clearly less morbid and expensive than classic surgery.

Disclosure: Nothing to disclose.
pathological diagnoses (non-neoplastic, adenoma, SSA/P, invasive cancer). The high diagnostic ability of EC-CAD to distinguish between adenoma and invasive cancer has already revealed in previous report [2]. As a next step, we conducted a prospective study to evaluate the real-time use of the current system.

Aims and Methods: The primary endpoint of this study was to verify the positive predictive value (PPV) in distinguishing invasive cancer from other lesions was 90% or higher when EC-CAD was applied for examination. This prospective study was conducted at Showa University Northern Yokohama Hospital from June 2017 to December 2017. In this study, we used the software constructed based on EC images obtained by staining cell nuclei with 1.0% methylene blue. At the start of the study, we used software that let the system learn 16000 images. During the study period, we made an update 3 times (the number of learning images for the system: 1st 18966 images, 2nd 32265 images, 3rd 36586). The subjects were colorectal lesions of 2mm or more in diameter which histological evaluation was performed after EC observation. Regarding the diagnostic results given by the EC-CAD, since a plurality of endoscopic images were acquired from one lesion, the majority decision method adopting the most frequent diagnostic result was used as a first diagnosis of the system. As a sub analysis, the endoscopists were divided into experts and trainee based on the difference in experience, and it was examined whether procedure time and diagnostic accuracy using EC-CAD were affected by the expertise.

Results: A total of 106 colorectal lesions (4 non-neoplasms, 34 adenomas, 68 invasive cancers (10 T1 cancers, 58 T2-T4 cancers)) from 99 patients were included. 77% (6434/8313) of the acquired EC images were able to be diagnosed by EC-CAD. Regarding the diagnostic performance of EC-CAD to distinguish invasive cancers from other lesions, sensitivity, specificity, accuracy, PPV and negative predictive value (NPV) were 93%, 97%, 94%, 98% and 88%, respectively. Considering experts and trainees separately, the sensitivity, specificity, accuracy, PPV, NPV were 93% vs. 93%, 97% vs. 100%, 94% vs. 94%, 98% vs. 100% and 89% vs. 67%, respectively. The time taken for EC image acquisition was 5.6 seconds on average. There was no significant difference in image acquisition time between experts (5.5 sec) and trainees (6.3 sec).

Conclusion: It suggested that EC-CAD will provide a reliable diagnosis with PPV 90% or higher in distinguishing invasive cancer from other lesions, regardless of the experience of endoscopists.

Introduction: Colorectal cancer has emerged as the main diagnostic and therapeutic tool in the detection of colonic adenomas. Training future endoscopists is essential to meet future demands.

Aims and Methods: In this study we have shown somewhat conflicting results regarding the influence of trainee-participation on adenoma detection rates (ADR), mostly showing positive or indifferent effects of trainee participation. A previous prospective study by our group showed no adverse effect of trainee participation on ADR. This study did not include first year trainees or subsequent surveillance exams. The aim of the current investigation was to see, whether the inclusion of first year trainees magnifies the noted difference and whether trainee participation affects ADRs or the timing of subsequent surveillance exams. A retrospective analysis of average-risk screening colonoscopies over a 3-year interval was performed. Patients with poor preparation were excluded. The final analysis included 4922 screening colonoscopies between the years 2004-2006, as well as 2184 subsequent surveillance exams. Data were collected from pathologic and endoscopic electronic data bases. The primary outcome was the ADR at colorectal polyps with and without early-stage colorectal cancers.

Results: Trainees participated in 1131 (23%) screening exams and in 232 (11%) surveillance exams. ADR did not significantly differ (p = 0.19) for screening exams with trainee participation (19.5%) or those without (21.4%). ADRs were generally higher at surveillance exams, both with (22.4%) and without (27.5%) trainee participation. The noted difference of ADRs at surveillance colonoscopies with or without trainee participation did not reach statistical significance (p = 0.1). Multivariate analysis showed no influence of first year fellow participation on the outcome. When surveillance recommendations differed from guidelines, shorter surveillance intervals were given more frequently if trainees participated during the initial screening procedure (p = 0.001).

Limitations: Single-center, retrospective study.

Conclusions: ADR did not significantly differ at screening or surveillance colonoscopies with or without trainee participation. There was a trend towards higher ADR at surveillance exams in both groups. The inclusion of first year trainees had no adverse effect on the outcome. However, trainee participation may result in shortened surveillance recommendations after initial screening exams.

Introduction: The development of a real-time robust detection system for colorectal neoplasms will significantly reduce the risk of missed lesions during colonoscopy. However, gaps in colonoscopy skills among endoscopists, primarily due to experience, have been identified, and solutions are critically needed.

Aims and Methods: To overcome this experience gap, we aimed to develop an artificial intelligence (AI) system that automatically detects early signs of colorectal cancer during colonoscopy.

Patients with and without colorectal polyps and those with colorectal cancer were included. A training data set of 5,000 images of 2,116 early-staged colorectal cancers or precursor lesions and 134,983 images of noncancerous tissue were provided. Using this training set, Deep Learning algorithms were provided to learn the colonoscopic features of the disease. The diagnostic accuracies and area under the receiver-operating characteristic curve of this algorithm as well as the processing speed of this AI system were measured by using validation set of 4,840 images (705 images with 752 lesions and 4135 images without lesions) from consecutive patients with and without early-staged colorectal cancers or precursor lesions.

Results: The sensitivity and specificity of the system were 97.3% (95% confidence interval [CI] = 95.9%-98.3%) and 99.0% (95% CI = 98.6%-99.2%), respectively, and the area under the curve was 0.975 (95% CI = 0.964-0.986) in the validation set. The sensitivities were 98.0% (95% CI = 96.6%-98.8%) in the polyoid subgroup and 93.7% (95% CI = 87.6%-96.9%) in the nonpolyoid subgroup. A supplementary human observational study demonstrated that the AI system had a superior diagnostic yield as endoscopists, including experienced, fellows, and beginners (Figure 1). The system analyzed all 4,840 images in 106.0 seconds (average, 21.9 ms/image), whereas endoscopists required median 725.2 seconds (IQR = 655-914) to analyze the 309 images. In addition, this system achieved in real-time detecting and displaying results of each video frame within 33 milliseconds (30 frames per second).

Conclusion: We have developed a real-time endoscopic image diagnosis support system using deep learning technology that automatically detects early signs of colorectal cancer during colonoscopy. This AI system can alert endoscopists in real time to avoid missing abnormalities such as polyps during colonoscopy, improving the early detection of this disease.

Introduction: Recent opinions have expressed that if an endoscopic diagnosis of adenomas can be made with high accuracy, then the omission of a pathological diagnosis following endoscopic resection is acceptable. Currently, there is no clear consensus regarding whether endoscopic treatment is required for all adenomas. Colonoendoscopy-based grading of dysplasia can be clinically effective for diagnostic purposes, if such a diagnosis of adenomas, particularly of low-grade adenomas, can be made with high accuracy.

Aims and Methods: In this study, we focused on the existence of mixed-pit pattern type I lesions in slit-like lumens, which is an endoscopiccytoscopic (EC) finding characteristic of adenomas, and investigated pathological findings that were correlated with this observation. We retrospectively examined 700 lesions among the neoplastic lesions that could be observed by EC between May 2005 and May 2017 and that were classified as EC2 according to the EC classification system and could be pathologically examined after endoscopic resection. Lesions characterized by mixed-pit pattern type I lesions were classified as EC2 normal pit (NP) sign (+), while those characterized by slit-like lumens only were classified as EC2 NP sign (−). We investigated the final pathological diagnosis results. In addition, we investigated the concordance rate of surveillance interval recommendation in EC diagnosis and pathological diagnosis based on USA guideline, and also examined the location, diameter, and morphological type of lesions to elucidate their clinical traits. In order to evaluate the concordance rate of EC 2 NP sign, 3 experts (T.K., Y.M. and M.M) and 3 trainees (T.W., T.K and K.M) reviewed digitally recorded EC images of the lesions.

Results: A total of 466 lesions were classified as EC2 NP sign (+). Of these, low-grade adenomas accounted for 450 lesions and advanced lesions (high-grade dysplasia, tubulovillous adenoma, invasive cancer) accounted for 16. NP sign (+) as an indicator of low-grade adenomas had a sensitivity of 85.4%, specificity of 90.8%, positive predictive value of 96.6%, negative predictive value of 67.1%, accuracy of 86.7%, and positive likelihood ratio of 9.23. It was 95.5% that the concordance rate of surveillance interval recommendation based on USA Guideline compared with EC and pathological diagnosis. Furthermore, an examination of the EC 2 NP sign (+) rate by location, diameter, and morphological type of lesions revealed that 75.7% were located in the proximal colon (p < 0.001), 81.4% of the lesions were ≤ 10 mm in diameter (p < 0.001). Further, 75.8% were of the flat/depressed type (p < 0.001). The interobserver agreement for the EC2 diagnosis following endoscopic resection is acceptable. Currently, there is no clear consensus regarding whether endoscopic treatment is required for all adenomas. Colonoendoscopy-based grading of dysplasia can be clinically effective for diagnostic purposes, if such a diagnosis of adenomas, particularly of low-grade adenomas, can be made with high accuracy.

PO1081 DEVELOPMENT OF A MODIFIED SMSA SCORING SYSTEM WITH IMPROVED ACCURACY IN THE PREDICTION OF COMPLICATIONS OF ENDOCYTOSCOPIC MUCOSAL RESECTION IN THE COLON

1 Hospital Frydek-Místek, Beskydy Gastrocentre, Internal Department, Frydek-Místek, Czech Republic
2 Hospital Frydek-Místek, University of Ostrava, Beskydy Gastrocentre, Internal Department, Frydek-Místek, Czech Republic

Contact E-Mail Address: ivanakaj@seznam.cz

Introduction: ADR (adenoma detection rate) is generally accepted quality indicator. For possible gaming with ADR other indicators are needed. MAP (mean adenoma per colonoscopy) reflects the quality of examination of entire colon and is considered to be the most objective quality indicator.

Aims and Methods: The aim of our study was to compare MAP with ADR and PDR (polyp detection rate) of all colonoscopists in our department. We retrospectively assessed the quality indicators of all colonoscopies performed in non-university hospital Frydek-Mistek from January 2013 to December 2017. We counted ADR, PDR and MAP for all colonoscopies in patients over 50 years of age excluding therapeutic, IBD, management of complications and sigmoidoscopy screening (screening, surveillance, diagnostic) and separately only for screening colonoscopies. Correlations between MAP, ADR and PDR were performed using Pearson’s correlation coefficient, p<0.05 was considered significant.

Results: The group for statistics comprised 6925 patients (3620 men, 3305 women, mean age 66.2 years). There were positive correlations between ADR of screening and pathological diagnosis. Furthermore, an examination of the EC2 NP sign among the 3 experts was 0.82, 0.90, and 0.94 and among the 3 trainees were 0.84 (T.K., Y.M.), 0.78 (T.K.-M.M.) and 0.82 (Y.M.-M.M.), respectively. The intraobserver agreement for the 3 experts agreed 0.84 (T.W.-T.K.), 0.86 (T.W.-M.K.) and 0.98 (T.K.-M.M.), and the 3 trainees were 0.80, 0.80 and 0.86, respectively.

Conclusion: These results suggest that when using EC for diagnosing colorectal neoplastic lesions, NP sign is a good indicator of low-grade adenomas with the EC2 classification. It was suggested that EC diagnosis could make it easier to determine whether endoscopic treatment is needed or not. Furthermore, the NP sign (+) rate tended to be high in lesions located in the proximal colon, that were ≤ 10 mm in diameter, and that were of the flat/depressed type.

Disclosure: Nothing to disclose

References
colono-scopies performed in non-university hospital Frydek-Mistek from January 2011 to October 2017 were counted ADR in all colonoscopies over 50 years of age excluding therapeutic, IBD, management of complications and sig-moido-scopies (screening, surveillance, diagnostic) and separately only for screening colonoscopies. Correlation analysis was performed using Pearson’s correlation coefficient, multiple chi square test was used to compare patients’ age and one anoVA was used to compare proportion of men and women among endoscopists, p < 0.05 was considered significant.

Results: In study period, 10472 colonoscopies and sigmoido-scopies were done in total. The number of polyps in the left colon becomes < 1 (F = 39.82 p < 0.001).

Conclusion: Right-sided colon polyps more likely to have dysplasia compared with left-sided polyps. Therefore, missing a polyp in the right colon is likely more significant than missing one in the left colon and guidelines should focus a stratification on the proximal colon and provide feedback to endoscopists regarding their proximal adenoma detection rates.

Differences in proportion of men and women (p = 0.048) and age of patients (p = 0.002). This should be taken into consideration when comparing various endoscopists but it does not affect the correlation analysis of ADR from all and screening colonoscopies. ADR for screening and surveillance were higher than for diagnostic colonoscopies in all endoscopists, ADR for all colonoscopies were lower than for screening but sufficiently by over 25 %, see the table. There was positive correlation between ADR of screening and all colonoscopies (r = 0.008 p < 0.005).

N ADR N ADR N ADR
Endoscopist N all ADR all screening surveillance ADR diagnostic
1 1467 39.1 567 41.3 380 45.3 520 32.1
2 419 47.0 146 49.3 186 52.7 87 31.0
3 815 37.7 170 40.0 226 48.7 419 30.3
4 1394 41.7 430 49.3 379 44.6 585 39.4
5 2466 45.0 700 48.5 597 52.8 1117 38.9
6 424 48.6 86 57.0 115 47.0 223 46.2

Conclusion: Calculation of ADR for all colonoscopies was possible in our department and there was positive correlation with ADR for screening colonoscopies. Because of inclusion of diagnostic examinations, ADR for all colonoscopies was lower than for screening but still over recommended values.

Introduction: We established a new procedure, laparoscopic endoscopy cooperative surgery (LECS) procedure to overcome the limitations of endoscopic resection (ER) for colorectal tumors. This procedure involves full thickness resection using a combination of laparoscopic assisted colectomy (LAC) and endoscopic submucosal dissection (ESD), which is quite different from the conventional method. In this report, we clarify the feasibility of performing a safe full-thickness resection with an adequate surgical margin by LECS with ESD.

Aims and Methods: The aim of this study is to clarify the feasibility of performing a full-thickness resection with an adequate surgical margin by LECS with ESD. We performed full-thickness resection for 17 colorectal tumors in 17 patients (male: female 10:7; mean age, 66.5 years) by LECS. The clinicopathological outcomes of these 17 cases and the feasibility of full-thickness resection were evaluated retrospectively.

The indications for LECS in patients with colorectal tumors were as follows: 1) intra-mucosal carcinoma (Tis) and adenoma with high-grade atypia (Vienna Classification, Category 3, 4) accompanied by wide and severe fibrosis in the submucosal layer (tumor recurrence after endoscopic or surgical resection), 2) intra-mucosal carcinoma (Tis) and adenoma with high-grade atypia involving the diverticulum or appendix, and 3) involving intraluminal or intramural growth-type submucosal tumors.

Results: We successfully performed full-thickness resection using LECS in 17 cases (Tis cancer [n = 6], adenoma [n = 9], schwannoma [n = 1], and gastro-intestinal stromal tumor [GIST] [n = 1]). The average tumor diameter was 22.4mm (range, 8-41mm). LECS was successfully performed in 17 all cases without conversion to open surgery: the R0 rate was 100%. The indications for LECS were as follows: involvement of the mucosa of the appendix (n = 6), tumor accompanied by severe fibrosis (n = 5), involvement of a diverticulum (n = 3), submucosal tumor (n = 2), and poor endoscopic operability (n = 1). We experienced no complications (e.g., leakage or gastrointestinal stenosis), and the median hospital stay was 6.4 days (range, 4 to 12 days). All 17 patients who were followed for ≥3 months (average, 30.8 months; range, 3-72 months) showed no residual or local recurrence. Thus, the use of the ESD technique in LECS, can achieve a safe oncological margin in cases involving colorectal tumors. Furthermore, a high complete resection rate, with an adequate surgical margin and a lower local recurrence rate can be expected.

We developed a LECS procedure to overcome the limitations of colorectal ESD, and completed the full-thickness resection of tumors that were considered to have a high risk of perforation. LECS was a safe, feasible, minimally-invasive procedure that achieved the full-thickness resection of colorectal tumors and which showed excellent clinical outcomes.

Introduction: Colorectal cancer (CRC) is one of the most common causes of cancer-related death worldwide, colorectal endoscopic submucosal dissection (ESD) has spread rapidly as an effective treatment strategy for early-stage CRC. However, there is major concern about bleeding as a complication of this procedure. While some reports have been published on the management of delayed bleeding after colorectal ESD, there is no consensus on the optimal treatment protocol for situations where emergency colonoscopy is deemed necessary for delayed bleeding after ESD. The criteria for judgement for emergency
colonoScope remains unclear. In this study, we attempted to extract the risk factors. Aims and Methods: The data of 454 consecutive patients who underwent ESD at Chiba University Hospital from April 2017 to December 2018 were reviewed in this study. The watch and wait strategy is a protocol of delayed bleeding after colorectal ESD. The location of rectum, and lesion size \( \geq 40 \) mm were identified by multivariate analysis as being significantly and independently associated with bleeding after ESD (OR: 5.547, and/or moderate amount of hematochezia more than 5 times. If there were no cases which require emergency colonoscopy, blood transfusion, or serious condition caused by delayed bleeding under our watch and wait strategy".

Conclusion: Our results suggest that the location of rectum, and lesion size \( \geq 40 \) mm are independent factors of delayed bleeding after colorectal ESD, but there were no cases which require emergency colonoscopy, blood transfusion, or serious condition caused by delayed bleeding under our watch and wait strategy.

Introduction: Colonoscopy and endoscopic eradication of neoplastic lesions are effective for the reduction of colorectal cancer incidence. However, 26% of colorectal diminutive neoplasms were reported to be missed in one colonoscopy (1). To reduce the number of missed cases, we developed a prototype computer-aided detection (CADe) system for colonoscopy (2).

Aims and Methods: The aim of this study was to evaluate the performance of the developed CADe system for colorectal polyps by using recorded video data. To develop the CADe system, we collected 84 full high-definition colonoscopy videos from study participants who underwent total colonoscopy from April 2015 to October 2015 at Showa University Northern Yokohama Hospital. Each colonoscopy video recorded from coaxial injection to withdrawal was visually analyzed across the anus. Therefore, these videos included polypos-negative and polyph-negative frames. Regarding the machine learning process, 2 expert endoscopists annotated all the frames regarding the presence or absence of a polyp. These videos included 166 polypos. The video data of 105 polypos were randomly selected, and 80-min polypos-negative videos were used for machine learning. If the system detects a polyp in the frame, it outputs an alert. To evaluate the performance of the system, we extracted 61 polypos-positive videos and 20-min polypos-negative videos from the study materials as validation sample. The percentage of correctly detected polyph and false-positive detection rate for the negative frames were calculated using the validation sample. Correct detection by the system was defined as a system output of an alert for more than half the length of each polyph-positive video.

Results: The system correctly detected 92% (56/61) of the polyps. Regarding morphological assessment, 92% (36/39) of flat lesions and 91% (20/22) of prolapsed lesions were identified as true-positive. The false-positive detection rate was 59% (19,680/33,088 frames). The system correctly detected 92% (56/61) of the polyps. Regarding morphological assessment, 92% (36/39) of flat lesions and 91% (20/22) of prolapsed lesions were identified as true-positive. The false-positive detection rate was 59% (19,680/33,088 frames).

Conclusion: The results showed that artificial intelligence has the potential of developing a CADe system for colorectal polyps by using recorded video data. To develop the CADe system, we collected 84 full high-definition colonoscopy videos from study participants who underwent total colonoscopy from April 2017 to December 2018. If the system detected more than half of the polyps, it was defined as a true positive. The polyph-negative videos were divided into 2 groups: bleeding group (27 neoplasms), and no-bleeding group (377 neoplasms). In bleeding group, there are no cases which require emergency colonoscopy for hemostasis after delayed bleeding under this watch and wait strategy. The location of rectum, and lesion size \( \geq 40 \) mm were identified by multivariate analysis as being significantly and independently associated with bleeding after ESD (OR: 5.547, respectively; p<0.05 for all).

Conclusion: Our results suggest that the location of rectum, and lesion size \( \geq 40 \) mm are independent factors of delayed bleeding after colorectal ESD, but there were no cases which require emergency colonoscopy, blood transfusion, or serious condition caused by delayed bleeding under our watch and wait strategy.

1. Ajioka S, Noma Y, Sato T, et al. Artificial intelligence-assisted polyp detection during colonoscopy: clinical performance for recognizing anatomical locations of colonoscopic images, which may be useful to acquire such skills is overcoming the difficulty in recognizing anatomical locations during colonoscopy. Recently, various computer-aided diagnosis (CAD) systems with deep convolutional neural networks (CNN) have achieved remarkable performance in many medical fields including the diagnosis of colorectal diseases. A CNN system that can recognize anatomical locations during colonoscopy may assist undertrained practitioners efficiently.

Aims and Methods: We constructed a CAD system with CNN based on GoogLeNet architecture to categorize colonoscopic images according to anatomical locations. 7 anatomical categories were used; terminal ileum, cecum, ascending colon to transverse colon, descending colon to sigmoid colon, rectum, anus and indistinguishable image. We retrospectively obtained images that were taken during total colonoscopy performed from January, 2017, to November, 2017, at single center in Japan. We used 9995 images of 409 cases for training the CNN system, and independent 5121 images of 118 cases for validating its performance. For each validation process of an image, the CNN system provided a probability score ranging from 0 to 100%, which indicates the probability for which category an image would belong to. We drew receiver operating characteristic (ROC) curve and calculated the area under the curves (AUC) by each category.

Results: In the validation process, the CNN system correctly recognized 66.6% of images (3410/5121). The rates of correct recognition by each anatomical category were 69% (145/209) for terminal ileum, 30% (211/683) for cecum, 51% (891/1715) for ascending to transverse colon, 99% (182/183) for descending to sigmoid colon, 23% (199/867) for rectum, and 91% (182/199) for anus, respectively. The specificity for each category were 99% for terminal ileum, 98.2% for cecum, 93.8% for ascending to transverse colon, 60% for descending to sigmoid colon, 98.1% for rectum, and 97.8% for anus. The calculated AUCs by the ROC curves were more than 0.8 for each anatomical category; 0.979 for terminal ileum, 0.940 for cecum, 0.875 for ascending to transverse colon, 0.846 for descending to sigmoid colon, 0.835 for rectum, and 0.992 for anus. The CNN system showed 97% images with a probability score of more than 99% that showed 91.7% accuracy in total.

Conclusion: We constructed the new CNN system with clinically relevant performance for recognizing anatomical locations of colonoscopic images, which may reduce the burden and time of acquiring the colonoscopic technique for beginners.

relationship between histology and pit pattern (p<0.01). According to LSTs, all 182 LST-Gs with a non VN pit pattern were intraepithelial neoplasias and SM-minute Ca cases. In 22 SM-deep Ca cases of LSTs, all 11 LST-Gs showed a type VN pit pattern, while only 2 cases in 11 LST-NGs showed a type VN pit pattern. There was significant relationship between subtypes and pit pattern in submucosal deep invasion of LSTs (p<0.01).

Conclusion: We suggest that the treatment for early-stage colorectal tumors greater than 20mm should be determined on the basis of the morphology and pit pattern by magnification colonoscopy. It is necessary to consider surgical resection for most of depressed and sessile polypoid-types because of the high rates of submucosal deep invasion. According to LSTs, LST-Gs with a type VN pit pattern are possible to allow of endoscopic piecemeal mucosal resection because of absence of SM-deep Ca cases, while LST-NGs should be considered a definite indication for ESD. Furthermore, it is necessary to obtain en-block specimens for precise histological assessment, because a few SM-deep Ca cases with a type VN pit pattern cannot be correctly diagnosed despite of using magnification endoscopy.

Introduction: Endoscopic submucosal dissection (ESD) evolved as a method for en bloc resection of large early-stage gastrointestinal tumours for accurate histopathologic evaluation in Japan. colorectal endoscopic submucosal dissection (ESD) can be technically difficult for various reasons, such as submucosal fibrosis. A thin muscular layer can lead to increased perforation rates and longer procedure times. Novel strategies, such as the submucosal pocket formation method, have been reported to overcome these difficulties. Additionally, we recently introduced a new technique, submucosal pocket creation using a traction device (TD). This device is designed to be fixed with clips on the free edges of a mucosal overlay to deflect the diseased mucosa away from the dissection plane during submucosal dissection. When colorectal ESDs are initially performed, we use this technique to facilitate a safe and efficient procedure.

Aims and Methods: We aimed to evaluate the utility of submucosal pocket creation using the TD during colorectal ESD as required by trainee endoscopists. At the Cancer Institute Hospital of Japanese Foundation for Cancer Research from January to March 2018, we retrospectively investigated outcomes of 82 colorectal ESDs performed by 2 groups of endoscopists (A and B). Group A comprised 5 endoscopists with less than 50 cases of colorectal ESD experience and group B comprised 5 endoscopists with more than 500 cases of colorectal ESD experience. ESDs were performed using a novel second-generation endoscopy that allows diagnostic imaging at 520× magnification. In the EC classifications, lesions diagnosed as EC3a vary extensively from adenoma to SM-m, including some lesions that are not suitable for endoscopic treatment. Therefore, to improve the accuracy of the depth of invasion using the EC classification, we investigated the presence or absence of 2 factors; high degree of nuclear enlargement (HNE) and multilayered nuclei (MNs), that are indicators of SM-m.

Aims and Methods: Between May 2005 and March 2018, we retrospectively evaluated 117 EC3a lesions diagnosed as EC2 or EC3, according to the EC classification. We subclassified EC3a into 2 grades (low grade and high grade) and defined low grade as not recognizing both HNE and MNs, and high grade as for any of the 2 factors. We examined the diagnostic accuracy of SM-m based on this ECa subclassification. In addition, we compared the diagnostic ability of EC for SM-m with that of other modalities; narrow-band imaging (NBI) and pit pattern.

Results: The sensitivity, specificity, positive predictive value, negative predictive value, accuracy, and positive likelihood ratio for the diagnostic accuracy of the ECa subclassifications were 90.4%, 91.5%, 81.0%, 96.0%, 91.2%, and 10.7 (p<0.001). Diagnostic performance for predicting SM-m or worse among EC, NBI and pit pattern is as follows: The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy about EC were 96.8%, 92.4%, 96.6%, 92.8%, 95.4% respectively. On the other hand, those of NBI were 98.6%, 52.2%, 83.7%, 93.9%, and 84.6%, and pit pattern were 96.1%, 83.3%, 93.4%, 95.7%, 92.4%, respectively.

Conclusion: From the EC findings, the presence of HNE, and MNs are important risk factors for SM-m or worse outcomes. Furthermore, the ECa subclassification taking account of these findings could be effective for the diagnosis of SM-m or worse.

P0193 EARLY-STAGE COLORECTAL PROTRUDED TUMOR WITH DEPRESSION MAY ORIGINATE FROM “DE NOVO” CANCER

Kobe Red Cross Hospital, Gastroenterology and Hepatology, Kobe, Japan

Contact E-Mail Address: h-miyazaki@kobe.jrc.or.jp

Introduction: It is widely accepted that the majority of colorectal cancers develop through polypoid growth. However, recent studies have shown that depressed tumors also contribute to the development of colorectal cancers. According to careful observation during colonoscopy, a protruded tumor with depressed morphology sometimes develops into a depressed-type tumor, which suggests that the bases are covered with normal mucosa. On the other hand, all 81 tumors without depression showed type III, IV or V pit patterns, which suggests that the bases are covered with neoplastic glands. There was significant relationship between the presence of depression and histology of the bases of protruded SM-Cas.

Conclusion: Our findings suggest that the treatment for early-stage colorectal protruded sessile tumors should be determined on the basis of the detection of depressed morphology and pit pattern diagnosis by magnification colonoscopy. It is necessary to consider surgical resection for the protruded tumors with depression, because they are all submucosal invasive carcinoma cases. Also, they may originate from what we call de novo cancers, depressed-type tumors, because all their cases are submucosal invasive carcinomas regardless of their size and have no adenomatous glands and moreover their bases are covered with normal mucosa. Therefore, we should always pay attention to protruded tumors with depression during colonoscopy.

Introduction: Cold forceps polypectomy (CFP) is often used to remove diminutive polyps. It does not induce thermal damage to tissue, and therefore has few complications such as postoperative bleeding and perforation. Other advantages are that it can be implemented using routine biopsi techniques, and the resected tissue can be recovered easily and reliably after resection. In addition, jumbo biopsy forceps are considered superior to standard forceps for removing colorectal polyps. The observation to check the margin of resected resections are enhanced with narrow band imaging (NBI)-enhanced endoscopy can also improve complete resection rate. However, in such cases, we sometimes experience local recurrence cases, the issue of features of them have not been clarified in detail.

Aims and Methods: In this study, we examined the clinicopathological features of local recurrence after jumbo forceps assisted by NBI endoscopy for patients with diminutive polyps. This multicentre, prospective, single-arm observational study was conducted at 11 institutes of the National Hospital Organization in Japan between January 2015 and September 2016. Patients aged 20–75 years with diminutive polyps were enrolled. A total of 504 patients were prospectively assessed, and 1015 polyps were resected. In addition, a total of 955 lesions were resected in the 471 patients who followed up 1 year after CFP to examine the polypectomy sites for local recurrence (follow-up rate, 94.1%). We analysed the local recurrence rate, clinicopathological characteristics of primary polyps and local recurrent polyps, as well as resection rates and adverse events.

Results: Local recurrence occurred in 20 (2.1%) cases of the 955 lesions subjected to flattening-assisted colonoscopy to standard colonoscopy. Improving ADR is the central focus of the current quality movement in colonoscopy. The fold flattening devices could ameliorate the ADR.

Aims and Methods: The aim of the study was to compare the efficacy of mucosal flattening assisted colonoscopy vs standard colonoscopy to improve the adenoma detection rate in patients undergoing colonoscopy. Secondary outcomes evaluated were: adenoma detection, procedure-related complications, patient satisfaction, and costs. The fold flattening devices could ameliorate the ADR.

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early colorectal neoplasms, and an insulation-tipped knife, hook knife, flush knife, or dual knife is conventionally used to perform ESD. However, because these devices are used without fixation to the target tissue, there is the potential risk of adverse events due to an unexpected incision or perforation. To reduce the risk of adverse events associated with a conventional knife when performing ESD, we used a scissors-type stag beetle (SB) knife Jr, which has a stretcher and an adequate dissection layer and prevents unexpected muscular layer injury. We previously reported that performing colorectal ESD with the SB knife Jr is easy, safe, and technically efficient. However, there is a need for more long-term clinical data to establish the full advantages of colorectal ESD with the SB knife Jr, with respect to favorable survival rates and very low recurrence rates.

Aims and Methods: The aim was to evaluate the long-term outcomes of ESD performed with the SB knife Jr for early colorectal neoplasms. ESD was performed for 163 lesions in 151 patients (male:female ratio = 78:73; mean age = 69 years) between October 2010 and March 2015. Data for 137 lesions in 126 patients (81%) who were followed up for more than 3 years were identified and analyzed. The en bloc resection rate, complete resection rate, curative resection rate, resected tumor size, procedural time, complications, and long-term outcomes, including local and distant recurrence rates, and survival rates were analyzed. 5-year overall survival rate was 97.5% (95% CI 95.3–99.7%), 3-year disease-specific survival rate (DSS) was 97.5%. The survival rates were analyzed for the entire study cohort, and the local and distant recurrence rates were analyzed for the cohort that underwent curative resection or those who were observationally managed through conservative treatment.

Results: The patients’ mean age was 68 ± 10 years, and the male:female ratio was 67:59. On histopathology, the prevalence rate for tubular adenoma was 29.9% (41/137), with Tis in 46.7% (64/137), T1a in 10.2% (14/137), and T1b in 13.1% (18/137). The mean resected tumor size was 32.1±16.5 mm, and the median procedure time was 80 (range, 15 - 420) min. The en bloc resection rate, complete resection rate, and curative resection rate were 97.8% (134/137), 94.2% (129/137), and 83.9% (115/137), respectively. No perforations occurred during the procedure. The delayed bleeding rate was 3.6% (5/137), rectal stricture occurred in one patient (0.7%) and was treated conservatively.

Conclusion: For long-term outcomes, the local recurrence rate was 1.6% (2/123), and no distant recurrence was observed in the recurrence analysis cohort. On survival curve, the 5-year overall survival rate was 97.5% (95% CI 95.3–99.7%), 3-year OS and DSS rates were 94.2%/92.1% and 99.0%/99.0%, respectively. 1 patient (0.7%, 1/137) died of colorectal cancer, and 9 (6.6%, 9/137) died of other diseases.

Secondary outcomes evaluated were: adenoma detection, procedure-related complications, patient satisfaction, and costs. The fold flattening devices could ameliorate the ADR.

when the ADR was greater than 40% using standard colonoscopy. Endocuff was clinically and statistically relevant when ADR with standard colonoscopy is lower than 25%, (O.R. 1.87 ITT analysis). About Ending no definitive conclusion could be drawn due to the scarce literature available, although the preliminary analysis did not show an advantage when compared to standard colonoscopy. Direct and indirect comparison between Ending vs Endocuff did not provide definitive conclusions.

P0197 FORWARD-VIEWING ENDSCOPE FOR ERCP IN PATIENTS WITH BILLROTH II GASTRECTOMY: A SYSTEMATIC REVIEW AND META-ANALYSIS

1Inje University Seoul Paik Hospital, Internal Medicine, Seoul, Korea (Republic of)
2Hallym University Chuncheon Sacred Heart Hospital, Internal Medicine, Chuncheon, Korea (Republic of)

Contact E-Mail Address: ptymd@hotmail.com

Introduction: The forward-viewing endoscope has been increasingly used to perform endoscopic retrograde cholangiopancreatography (ERCP) in patients who underwent Billroth II gastrectomy.

Aims and Methods: This study intended to assess efficacy and safety of the forward-viewing endoscope for ERCP in Billroth II gastrectomy patients compared with standard side-viewing endoscope using a systematic review and meta-analysis. A systematic review was conducted for studies that evaluated the outcomes of ERCP for patients with Billroth II gastrectomy. Random-effect model meta-analyses with subgroup analyses were conducted. The methodological quality of the included publications was evaluated using the risk of bias assessment tool for non-randomized studies. The publication bias was assessed.

Results: In total, 25 studies (1 randomized, 18 retrospective, 1 prospective, and 5 case series studies) with 2446 patients (499 forward-viewing and 1947 side-viewing endoscopes) were analyzed. The pooled afferent loop intubation rate was higher with the forward-viewing endoscope (90.3%, 95% confidence interval (CI):85.6-95.3% vs. 86.8%, 95% CI:82.8-89.9%). The pooled selective cannulation rate was higher with the side-viewing endoscope (92.3%, 95% CI:88.0-95.2% vs. 91.1%, 95% CI:87.2-93.8%). The pooled bowel perforation rate was higher with the side-viewing endoscope (3.6%, 95% CI:2.3-5.7% vs. 3.0%, 95% CI:1.7-5.3%). The pooled pancreatitis rate was higher with the forward-viewing endoscope (5.4%, 95% CI:3.6-8.0% vs. 2.5%, 95% CI:2.3-5.7%). The pooled afferent loop intubation rate was higher with the forward-viewing endoscope (3.0%, 95% CI:1.6-5.5% vs. 2.0%, 95% CI:1.4-3.0%). The heterogeneity among the studies was not significant. The publication bias was minimal.

Conclusion: This meta-analysis indicates that the forward-viewing endoscope is as safe and effective as conventional side-viewing endoscope for ERCP in patients with Billroth II gastrectomy.

P0198 LIVER HYDATID CYST - WHEN DO WE NEED BILIARY STENTING IN MANAGEMENT PROTOCOL. A STUDY OF 56 CASES

S. Jagannath, S. Chintani1, S. Prasad1

1Surat Institute Of Digestive Sciences, Endoscopy, Surat, India
2Surat Institute Of Digestive Sciences, Surat, India

Contact E-Mail Address: drp.desai@hotmail.com

Introduction: Hydatidosis, a zoonotic infection, is due to the larval stage of the tapeworm Echinococcus (E.). The outer lamina of a cyst, the acotyl or peri- cyst, is formed by compressed and fibrotic host tissue and may become calcified, whereas inner layers are of parasitic origin and act as a germinal centre. A cyst may or may not contain daughter cyst(s). Secondary echinococcosis can develop where cyst contents are released. The cyst, is formed by compressed and fibrotic host tissue and may become calcified, than large peripheral cysts.

Cyst which is near to hilum has more chances of biliary communication rather due to cyst internal rupture. None of the patients had recurrence in our present series, in average follow up of 3 months. 1 patient had fluid collection which was treated with percutaneous drainage.

Conclusion: Cystectomy - a non radical alternative of hydatid disease is practical and feasible approach.

P0199 COMPARISON OF DEXMEDETOMIDINE WITH MIDAZOLAM VERSUS MIDAZOLAM ALONE FOR SEDATION DURING ERCP: A PROSPECTIVE OBSERVATIONAL STUDY

K. Yamakita1, Y. Kitano1, K. Takahashi1, H. Iwamoto1, T. Ota1, A. Tsure1

1Asahikawa Medical University, Asahikawa, Japan

Contact E-Mail Address: keisuke_yamakita@yahoo.co.jp

Introduction: Dexmedetomidine (DEX) is a highly selective α2-adrenergic agonist that elicits sedative and analgesic effects in humans. Recently, DEX has been used for endoscopic sedation. However, the usefulness and safety of DEX for sedation during endoscopic procedure has not been fully evaluated.

Aims and Methods: The aim of this study was to compare the efficacy and safety of standard sedation using midazolam (midazolam group) with combination sedation using DEX and midazolam (midazolam+DEX group). A prospective, observational study was conducted in 89 patients who underwent ERCP. Written informed consents were obtained from all patients before enrollment. Satisfaction score among patients were evaluated with Visual Analogue Scale. Body motion during sedation (1–5 represents discontinuance of procedure), vital signs, and recovery time were assessed.

Results: 46 patients were administered with midazolam alone (midazolam group) and 43 patients were administered with DEX and midazolam (midazolam+DEX group). The baseline characteristics and procedure time were similar between the 2 groups. Body motion was significantly lower in midazolam+DEX group than in midazolam group (1.5 vs. 2.58, p<0.0001). Satisfaction score, recovery time, respiratory depression, hypotension and bradycardia were not significantly different between the 2 groups.

Conclusion: The present study suggests that a combination of DEX and midazolam is as safe as midazolam alone for sedation during ERCP. This combination has less body motion than midazolam alone without extending recovery time.

P0200 UTILITY OF ENDOSCOPIC RETROGRADE CHOLANGIPANCREATOGRAPHY FOR THE MANAGEMENT OF SYMPTOMATIC Pancreas Divisum IN CHILDREN: EXPERIENCE FROM A SINGLE CENTER IN CHINA

G-X. Cui, J. Yang, W. Lu, L. Lu, X. Zhang

Hangzhou First People’s Hospital, Gastroenterology and Hepatology, Hangzhou, China

Contact E-Mail Address: 16258854574@163.com

Introduction: Pancreas divisum (PD) is the most common congenital anomaly of the pancreas. Most PD individuals are asymptomatic, but a few may present symptoms in the form of recurrent acute pancreatitis (RAP), chronic pancreatitis (CP) or pancreatic-type pain. Currently, most PD-related studies published in the literature have been limited to adults. Clinical data in pediatric PD are relatively insufficient. However, it is important to early diagnose and timely treat symptomatic PD, especially in children for the better clinical outcomes.
Aims and Methods: To estimate the safety and efficacy of endoscopic retrograde cholangiopancreatography (ERCP) for the treatment of symptomatic PD in children. We retrospectively analyzed patients of symptomatic PD(PD-P) who were younger than 18 years old from January 2011 to December 2017 in our institute. The PD-P included PD with RAP (RAP group) and PD with CP (CP group). All children were under 18 years of age as a main therapy. During an ERCP, minor endoscopic sphincterotomy combined with dorsal duct stenting(Mi-ESCS) was performed for complete PD (CPD) patients, and Bi-papilla ESCS (Bi-ESCS) was performed for incomplete PD (IPD) patients. ERCP-related data, complications, cholangiographic data were collected and analyzed. Long-term follow up was carried out to observe occurrence of developing CP in RAP group, children’s recovery, as well as their weight, growth and intelligence.

Results: A total of 312 pediatric ERCPs were performed for 157 children during this period. Of which 34 were PD-P cases, among which 30 were s-PD. The endoscopic detection rate of PD was 21.7%. Of the 30 s-PD patients, 19 were PD with RAP, among which 17 were CPD and 2 were IPD. The other 11 were PD with CP, among which CPD and IPD were 7 and 4 respectively. A total of 84 attempted ERCPs were performed among which 44 were for RAP group and 40 for CP group. The success rate of cannulating the minor papilla was 97.6% (82/84). The total response rate to endorhesis was 93.3%, with that of 100% (19/19) in RAP group and 81.8% (9/11) in CP group. The 2 patients with no response to endorhesis in CP group underwent surgery. The mean interval of changing pancreatic dorsal duct stent is 3 months (from 2 to 6 months). The mean number of changing dorsal duct stent was 2.3 in RAP group and 3.6 in CP group. ERCP-related complications were mild with a rate 7.1% (23/325), all of which were managed conservatively. During follow up from 3 to 84 months (mean 38.1 months), all patients had patent relief. In RAP group, 2 patients developed CP with a rate of 10.5%, others showed no more dilation of dorsal ducts. In CP group, 1 patient had pain relief within few months of acute pancreatitis, however, they demanded multiple repeated changing dorsal stents with no obvious improvement in pancreatic duct. In both groups, children presented normal in weight, growth and intelligence.

Conclusion: Mi-ESCS and Bi-ESCS with ERCP are safe and effective methods to manage s-PD in pediatric patients. It seems very important for such children to undergo endoscopic interventions as early as possible in order to avoid developing CP. Children of PD with CP may present asymptomatic with long term ERCP therapy.

Disclosure: Nothing to disclose.

P0201 PANCREATIC DUCT PERFORATION DURING GUIDEWIRE CANNULATION FOR THERAPEUTIC BILIARY ERCP
J. García-Cano1, L. Taberna-Aranz2
1Hospital Virgen de la Luz, Gastroenterology, Cuenca, Spain
2Health District, Family Practice, Cuenca, Spain

Contact E-Mail Address: jgarcia59@gmail.com

Introduction: Guidewire (GW) cannulation of the common bile duct (CBD) in ERCP is becoming increasingly widespread. Inadvertent GW passage into the main pancreatic duct (MPD) is relatively common. As a consequence, sometimes it happens that MPD perforation occurs. The techniques of Mi-ESCS and Bi-ESCS with ERCP are safe and effective methods to manage s-PD in pediatric patients. It seems very important for such children to undergo endoscopic interventions as early as possible in order to avoid developing CP. Children of PD with CP may present asymptomatic with long term ERCP therapy.

3University of Pennsylvania Health System, Philadelphia, United States
4Weill Cornell Medical College, New York, United States

Contact E-Mail Address: amy.tyberg@gmail.com

Introduction: Endoscopic ultrasound guided biliary drainage (EUS-PD) is an efficacious, safe option for patients with pancreatic duct obstruction who fail conventional endoscopic retrograde cholangiopancreatography (ERCP). The procedure involves accessing the pancreatic duct using EUS, creating a fistulous tract, and deploying a decompressing stent across the tract. It is a technically challenging procedure, requiring advanced skills in EUS and ERCP. The aim of this study was to define the learning curve for EUS-PD.

Aims and Methods: Consecutive patients undergoing EUS-PD by a single operator with training in therapeutic endosonography, were included from a dedicated registry from May 2003 to September 2017. Demographics, procedure info, adverse events, and follow-up data were collected. Non-linear regression and CUSUM analyses was conducted for the learning curve. Technical success was defined as successful stent placement. Clinical success was defined as resolution of procedure indication.

Results: 55 patients were included (54%M, mean age 58 years). The majority of patients had benign disease (n = 51, 91%): chronic pancreatitis n = 26, anasto- motic leak n = 14, and s-PD n = 2. The remaining 4 patients had malignant obstruction. 25 patients (44%) had altered anatomy. Technical success was achieved in 47 patients (84%). Stent placement was transluminal in 43 patients (92%) and transpapillary in 4 (9%), antegrade in 36 patients (77%) and retro- grade in 4 patients (8%). Successful pancreatic stenting was achieved in 46/47 (98%) patients who achieved technical success. Adverse events were seen in 13 patients (6 of whom did not achieve technical success) and included bleeding requiring embolization (n = 5), bleeding treated with angiography, perforation requiring surgery (n = 1), pancreatitis (n = 5), and a pancreatic fluid collection drained via EUS (n = 2). Median procedure time was 80 mins (range 49–159 mins). CUSUM chart shows 80 minute procedure time was achieved at the 27th procedure indicating efficiency. Apart from 2 outliers, procedure durations further reduced with consequent procedures from 40ths onwards reaching a plateau which could be the plateau indicating mastery (nonlinear regression p < 0.0001)

Conclusion: Endoscopists experienced in EUS-PD are expected to achieve a repeatable, efficient procedure time of < 80 mins, in 95% of cases, when the procedure takes < 80 minutes and a learning rate of 27 cases. Continued improvement is demonstrated with additional experience, with plateau indicating mastery suggested at the 40th case. EUS-PD is probably one of the hardest therapeutic endosonographic procedure to learn and master.

P0203 EUS-GUIDED GALLBLADDER DRAINAGE: A LEARNING CURVE MODIFIED BY TECHNICAL PROGRESS
A. Tyberg1, S. Shah2, P. Kedia1, M. Gaidhane1, M. Kahaleh1
1Robert Wood Johnson Medical School Rutgers University, Gastroenterology, New Brunswick, United States
2Well Cornell Medical College, New York, United States
3Methodist Dallas Medical Center, Dallas, United States

Contact E-Mail Address: amy.tyberg@gmail.com

Introduction: Endoscopic ultrasound-guided gallbladder drainage (EUS-GBLB) is an efficacious, safe option for patients with cholecystitis who cannot undergo cholecystectomy. The procedure involves accessing the gallbladder using EUS, creating a fistulous tract, and deploying a stent across the tract. It is a technically challenging procedure, requiring skills in EUS, fluoroscopy, and stent deployment. The aim of this study was to define the learning curve for EUS-GBLB.

Aims and Methods: Consecutive patients undergoing EUS-GBLB by a single operator were included from a prospective registry from January 2012 to July 2017. Demographics, procedure info, post-procedure follow-up data, and adverse events were collected. Non-linear regression and CUSUM analyses was conducted for the learning curve. Clinical success was defined as resolution of cholecystitis post-procedure.

Results: 84 patients were included (58%M, mean age 76 years). 20 patients (42%) had malignant cholecystitis, the remaining had benign disease. Technical success was 100%. Most patients had lumen-apposing metal stents (LAMS) (15mm, n = 29, 60%; 10mm, n = 51, 17%), 25 of which were cautery-enhanced. The remaining patients had FCSEMS (n = 9, 19%) or plastic stents alone (n = 2, 4%). 1 patient required bridging stents placement. The majority of stents were transduodenal (n = 28, 38%), the remaining transgastric (n = 15; 31%) or trans- jejunial (n = 4, 8%), and 1 patient had 2 stents placed from transgastric and...
transudosal duct position during the same procedure. Clinical success was achieved in 97% of the remaining patients between 2008 and 2012, 7 were lost to follow-up and 3 had persistent cholecystitis. 9 patients (19%) had adverse events including bleeding (n = 4), liver abscesses (n = 2), and hypotension post procedure. 2 patients passed away post-procedure due to respiratory failure and peritonitis secondary to ruptured gallbladder wall. 6 patients required re-intervention for stent occlusion with repeat endoscopy or surgical cholecystectomy. The median procedure time was 41 minutes (range 16–121 mins). CUSUM chart shows 41 minute procedure was achieved at the 19th procedure hence indicating efficiency. Procedure durations following 10 procedures being between 90 minutes and undertow interquartile regression p < 0.0001 indicating continued improvement with experience. This also may be due to the introduction of cautery-enhanced LAMS.

**Conclusion:** Endoscopists experienced in EUS-GLB are expected to achieve a reduction in procedure time over successive cases, with efficiency reached at 41 minutes and a learning rate of 19 cases. Continued improvement is demonstrated with additional experience and the introduction of cautery-enhanced LAMS.

**Disclosure:** Michel Kaehler MD has received grant support from Boston Scientific, Fujionix, Emcision, Xlumena Inc., W.L. Gore, MaunaKea, Apollo Endosurgery, Cook Endoscopy, ASPBARIATRICS, GI Dynamics, NinePoint Medical, Merit Medical, Olympus and MI Tech. He is a consultant for Boston Scientific, Xlumena Inc., Concordia Laboratories Inc, AB&Bie, and MaunaKea Tech. Amy Tyberg MD is a consultant for EndoGastric Solutions. Prashant holds patents with additional experience and the introduction of cautery-enhanced LAMS.

**Contact E-Mail Address:** konparaskeva@gmail.com

**Introduction:** Endoscopy is the preferred approach for the diagnosis and treatment of bile duct stones. However, endoscopic retrograde cholangiopancreatography (ERCP) may be unnecessary. We conducted a retrospective, unicentric analysis of elective ERCP procedures (OR = 209.1, 95% CI 2.18–2050.8), normal total bilirubin (OR = 138.9, 95% CI 1.19–1627.2), ERCP performed in ≤7 days (OR = 32.9, 95% CI 1.08–1004.8) and removal of the stent in ≤12 weeks (OR = 40.7, 95% CI 1.11–160.9) were associated with resolution of the biliary leak and absence of another pathology (p < 0.005; r² = 0.71). The area under the ROC curve of these criteria for outcome prediction was 0.93 (p < 0.001). When ≥3 criteria were present (42.9%, of patients), the model presented specificity of 100% and predictive value of 45.8% in outcome prediction.

**Conclusion:** We identified criteria that allow selection of 43% of patients in whom repetition of ERCP after treatment of biliary leaks may be unnecessary. These patients can have their biliary stents removed by esophagogastroendoscopy, increasing safety and efficiency of healthcare resources utilization.

**Disclosure:** Nothing to disclose.

2Konstantopoulo, Athens, Greece

3Radiology, Konstantopoulo, Athens, Greece

Contact E-Mail Address: konparaskeva@gmail.com

**Introduction:** Single-operator cholangioscopy (D-SOC) was developed as a novel approach to enable direct and increased number of images, patient radiation doses can be high, especially in complex cases. A new digital single-operator cholangioscopy (D-SOC) system (SpyGlass Digital System, Boston Scientific) allows direct visualization of the ducts, targeted biopsies, visual wire manipulation and difficult stone lithotripsy in a radiation-free manner. We investigated whether the Spyglass platform used adjunctively to ERCP may actually reduce patient radiation exposure.

**Aims and Methods:** We retrospectively analyzed a prospective database of consecutive patients undergoing D-SOC following failure of ERCP either difficult-to-treat biliary stones or indeterminate strictures. The overall patient radiation exposure outcomes in terms of Kerma Area Product (KAP), Fluoroscopy time (T) and the total number of films (F) were compared to a control subgroup of patients who had their stents removed by esophagogastroduodenoscopy, and Apollo Endosurgery. - All other authors have nothing to disclose.

**Results:** A total of 43 patients were included, 62.8% (n = 27) female, mean age 58.2 ± 17.2 years. The most common etiology of biliary leaks was laparoscopic cholecystectomy (56.8%) and the most common location the cystic duct stump (33.5%). Technical success was 93.5%, with resolution of the biliary leak in 100% of patients. On multivariate analysis, elective ERCP procedure (OR = 209.1, 95% CI 2.18–2050.8), normal total bilirubin (OR = 138.9, 95% CI 1.19–1627.2), ERCP performed in ≤7 days (OR = 32.9, 95% CI 1.08–1004.8) and removal of the stent in ≤12 weeks (OR = 40.7, 95% CI 1.11–160.9) were associated with resolution of the biliary leak and absence of another pathology (p < 0.005; r² = 0.71). The area under the ROC curve of these criteria for outcome prediction was 0.93 (p < 0.001). When ≥3 criteria were present (42.9%, of patients), the model presented specificity of 100% and predictive value of 45.8% in outcome prediction.

**Conclusion:** We identified criteria that allow selection of 43% of patients in whom repetition of ERCP after treatment of biliary leaks may be unnecessary. These patients can have their biliary stents removed by esophagogastroendoscopy, increasing safety and efficiency of healthcare resources utilization.

Aims and Methods: The study aim was to assess if the terminal bile duct diameter can be determined by inspecting the major papilla morphology/width during duodenoscopy. Between July 2017 and January 2018, in 3 hospitals, all consecutive patients with naive papilla referred for ERCP were eligible for enrollment. The transverse diameter (tD) of the papilla was measured using a comparative measurement technique (biopsy forceps) and a novel software (validity and reliability tested). The papilla morphology was classified into 1 of 4 groups: non-proeminent, prominent, bulging, distorted. The tBD’s diameter was measured in the distal 1 cm (cholediagram acquired in supine/prone) in a workstation, by an independent researcher. Main outcome was evaluated using a Pearson correlation.

Results: Between July 2017 and January 2018, in 3 hospitals, all consecutive patients with naive papilla referred for ERCP were eligible for enrollment. The transverse diameter (tD) of the papilla was measured using a comparative measurement technique (biopsy forceps) and a novel software (validity and reliability tested). The papilla morphology was classified into 1 of 4 groups: non-proeminent, prominent, bulging, distorted. The tBD’s diameter was measured in the distal 1 cm (cholediagram acquired in supine/prone) in a workstation, by an independent researcher. Main outcome was evaluated using a Pearson correlation.

Conclusion: Despite what is suggested in the literature, the morphology and the width of the major papilla do not have any association with the diameter of the tBD, and consequently these 2 dimensions should not be taken into account when designing for a cannulation technique.

P0208 FEASIBILITY OF A NEW SHORT-TYPE DOUBLE-BALLOON ENDOCOSCOPE WITH ADVANCED FORCE TRANSMISSION AND ADAPTIVE BENDING FOR PANCREATOBILIARY INTERVENTION IN PATIENTS WITH SURGICALLY ALTERED ANATOMY: A PROPENSITY-MATCHED ANALYSIS

A. Yamada1, H. Kogure1, Y. Nakai2, N. Takahara3, S. Mizuno4, M. Tada1, K. Koike1

The University of Tokyo, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: yamada-a@umin.ac.jp

Introduction: Recently, short-type double-balloon endoscopes (DBEs) for pancreaticobiliary interventions in patients with surgically altered anatomy have become available in many institutions. However, we previously demonstrated in a multicenter study that endoscopic retrograde cholangiopancreatography (ERC) using a conventional short-type DBE is a lengthy procedure, requiring approximately 22 minutes to reach the target site and 56 minutes to complete ERCP-related interventions. A new short-type DBE has been developed with a major focus on facilitating scope insertion to the target site for pancreaticobiliary interventions in patients with surgically altered anatomy. Aims and Methods: We investigated the feasibility of this new short-type DBE by comparing it with a conventional DBE. Data from 885 ERCP procedures using balloon endoscopy were analyzed. We used propensity score matching to adjust for differences between patients who underwent the new DBE procedure and the new short-type DBE versus the conventional short-type DBE. The outcomes of interest were the success rate of reaching the target site, the success rate of the pancreaticobiliary intervention, the insertion time required to reach the target site, the overall procedure time, the success rate of cannulation of the papilla of Vater, the time to cannulation of the papilla of Vater, and adverse events during or after the ERCP procedure.

Results: A total of 163 pairs of patients were selected on the basis of propensity score matching. The success rate of reaching the target site was 100% in both the new DBE group and the conventional DBE group (p = 0.10). The new DBE group had a significantly shorter insertion time required to reach the target site than the conventional DBE group (10 min vs. 14 min, p = 0.01). The success rate of the pancreaticobiliary interventions in the new DBE group was as high as that in the conventional DBE group (92% vs. 89% p = 0.35). The overall procedure time decreased from 62 min in the conventional DBE group to 55 min in the new DBE group (p = 0.26). Apart from cholecystocholedochusintumus and pancreatojejuno-ostomy, the success rate of cannulation of the papilla of Vater in the new DBE group was higher than that in the conventional DBE group (96% vs. 87%, p = 0.10). No significant difference in the rate of adverse events was observed between the 2 groups.

Conclusion: A new short-type DBE allows faster insertion to the target site for pancreaticobiliary intervention in patients with surgically altered anatomy.

Disclosure: Nothing to disclose.

P0209 POSITIVE CORRELATION BETWEEN PANCREATIC PARENCHYMAL VOLUME AND PEP

Osaka City University Graduate School of Medicine, Osaka, Japan

Contact E-Mail Address: hiromaruyama99@gmail.com

Introduction: Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) remains a common and serious adverse event associated with ERCP. PEP after initial ERCP was reported to have an incidence ranging from 10% to 15% in various studies, and the mortality rate was 0.11%. PEP is considered a high-priority adverse event. Recently, preventative measures for PEP such as high-dose rectal diclofenac and pancreatic stent placement have been proposed as useful approaches. However, they may not be appropriate for all patients, given the risks involved. Therefore, in order to use these preventive methods more effectively, it is necessary to be able to easily stratify patients into the high- and low-risk groups for PEP.

The three major causes of PEP are patient-related factors, operator-related factors, and technique-related factors. It is difficult to predict the incidence of PEP because there are many potential factors in each category. We considered the importance of predicting PEP based on pre-ERCP findings because it may be possible to increase the safety of the endoscopic procedure. In a previous study, the degree of pancreatic exocrine function showed a significant positive correlation (p < 0.001) when determined using the 131I-labeled Breath Test and ancin cell area ratio. However, the risk associated with pancreatic parenchymal volume has never been examined as a risk factor for PEP. We hypothesized that a large pancreatic parenchymal volume would increase the risk of PEP. The pancreatic parenchymal volume of the pancreas was quantified using the volume analyzer SYNAPSE VINCENT® (Fujifilm Medical Co, Tokyo, Japan) in pre-ERC images and used to evaluate whether it could be a risk factor for PEP.

Aims and Methods: The aim of this study was to investigate the risk factors for PEP by quantification of pancreatic parenchymal volume using pre-ERC images. Overall, 800 patients were recruited from April 2012 to February 2015 for this study. There were 240 patients who satisfied the inclusion criteria. Measurement of pancreatic parenchymal volume was achieved using the volume analyzer SYNAPSE VINCENT® in all cases and was used to evaluate the risk factors for PEP.

Results: According to the criteria established by the consensus guidelines (Cotton classification), 23 patients (9.6%) were classified as having mild disease, 4 (1.7%) as having moderate disease, and 5 (2.1%) as having severe disease. Multivariate model analysis adjusted for age, female sex, pancreatic duct guidewire cannulation, precut sphincterotomy, and pancreatic injection showed that a large pancreatic parenchymal volume was a significant risk factor for PEP (odds ratio 1.12, 95% confidence interval 1.07–1.17; p < 0.01). In addition, a larger pancreatic parenchymal volume was significantly associated with a higher incidence of PEP (p < 0.001).

Conclusion: A large pancreatic parenchymal volume was identified as a risk factor for PEP. The results of this study suggest that pre-ERC images might be useful for predicting PEP. Additional caution should be required for patients with larger pancreatic parenchymal volumes to prevent PEP.

Disclosure: Nothing to disclose.

Introduction: The continuous monitoring of quality indicators in gastrointestinal endoscopy became an essential requirement nowadays. Most of these data cannot be extracted from the currently used free-text reports, therefore a...
web-based data collecting system, the Hungarian ERCP Registry was developed. Here we present the first multicentre data from the registry.

**Aims and Methods:** Data collection started in January 2017 at University of Pécs, and a further 4 centres (Szeged, Debrecen, Budapest and Szombathely) started to use the registry from a later date.

Regarding the ERCP data, 884 patients were recorded in the database until March 2018 in the 5 participating centres. 30-day follow up data was collected to detect all procedure related late complications, this data is available in 73.5% of the procedures. Native papilla (NP) was detected in 698 ERCPs (62.5% of all procedures). The success rate of biliary cannulation was 90.5% in these patients. Post-ERCP pancreatitis (PPE) developed in 22 cases (3.2% of procedures with NP), clinically significant bleeding was reported in 14 patients (2.0% of cases with NP). Cholangitis was observed in 18 cases (1.6% of all procedures), and pancreatitis in 16 cases (1.4%). Endoclips suppository was placed in 43.8% of the cases, while prophylactic pancreas stent was applied in 9.5% of the procedures to prevent PEP. The data of the participating centres are shown below. Center/ERCP number/36 f/U (%)/NP in ERCP (%)/Success in NP (%)/Comp. rate (%)/PPE/Bleed/Cholang. /Perf.: Pécs/692/75.1/62.6/89.6/3.2/1.4/0.7/1.9; Szeged/207/67.6/66.2/94.2/3.9/3.1/1.0; Budapest/151/69.5/55.6/89.3/3.1/2/1.2/3.3/0.0; Debrecen/35/85.7/57.1/100/11/0.0/0.0/0/0; Szombathely/32/81.5/73.3/4.2/2/0/0.0/0/0.

**Conclusion:** These are the first prospectively collected multicentre key performance indicators from the Hungarian ERCP Registry. This web-based registry is a suitable tool to detect the quality of patient care and also be used for clinical research. Further centres are encouraged and welcome to join this project.

**Disclosure:** Nothing to disclose.

**P0211 USE OF THE FORWARD-VIEWING ENDOSCOPE CAN BE A RISK FACTOR FOR POST-ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOSCOPY PANCREATITIS: A PROSPECTIVE MULTICENTRE OBSERVATIONAL STUDY**

**K Chikugo1, B Endoh1, Y Mizumoto1, Y Nakai2, K Kusumoto2, Y Itokawa2, T Suzuki1, T Kawakami1, A Suzuki3, O Inatomi5, S Bamba5, K Tanaka4**

**Aims and Methods:** A forward-viewing endoscope is used for endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered anatomy such as Billroth II type or Roux-en Y type reconstruction. Difficulty in performing cholangiopancreatography (ERCP) in patients with surgically altered anatomy is often encountered. The forward-viewing endoscope has been used in such cases. In the present study, the diagnosis of post-ERCP pancreatitis (PPE) was performed in patients with altered anatomy who underwent ERCP with the forward-viewing endoscope. A total of 1877 patients were analysed, from 7 high-volume hospitals in Japan were enrolled (SOSUI study). We excluded patients with acute pancreatitis, biliary-enteric anastomosis, failure to reach the ampulla, altered anatomy other than Billroth II or Roux-en Y reconstruction, and the use of rescue techniques (rT) can be conditioned, among other factors, by the papillary morphology.

**Results:** Use of the forward-viewing endoscope in ERCP is a risk factor for PEP. Some authors suggest that the difficulty of biliary cannulation and the use of rescue techniques (rT) can be conditioned, among other factors, by the papillary morphology.

**Conclusion:** The success rate of biliary cannulation (tbc), difficult cannulation and rT. The influence of papillary morphology on the performance of the 2 lithotripsy modalities.

**Disclosure:** Nothing to disclose.

**P0212 SINGLE-OPERATOR HEBRAL CHOLANGIOPANCREATOSCOPY-GUIDED LITHOTRIPSY FOR DIFFICULT BILIARY AND PANCREATIC STONES - A PROSPECTIVE MULTICENTER STUDY**

**J Fernandes1,2, G Alexandri1,2, L Lourenço3, P Barreiro4, D Horta5, S Giester6, T Araújo7, D Libânio7,8, J Reis2, T Bana e Costa3, L Lopes1,2,6,7,8, J Canena1,2,3**

**Aims and Methods:** We intended to evaluate if the duration of biliary cannulation, the existence of a difficult cannulation and the use of rT are influenced by the papillary morphology.

**Conclusion:** This was a multicenter (3) prospective cohort study, including consecutive patients referred for ERCP with naïve papilla between August 2017 and January 2018, performed by experienced endoscopists (~ 4000 CPRE). The prevalence of biliary stones is very effective and is associated with transient and mild complications. There is a clear need for comparative studies between EHL and rT.

**Disclosure:** Nothing to disclose.

**P0213 DOES THE MORPHOLOGY OF THE MAJOR PAPILLA INFLUENCE BILIARY CANNULATION? - A MULTICENTER PROSPECTIVE STUDY**

**J Fernandes1,2, I Costa1,2, J Fonseca1, S Giester1, T Araújo1, D Libânio1,3, D Martins-Ares1,2, G Alexandri1,2, D Horta3, L Lourenço1,3, J Reis2, J Ramada1,2, C Meireles Simões1,2, J Canena1,2,3, L Lopes1,2,3,4,5,6**

**Introduction:** Recent, the availability of single-operator cholangiopancreatoscopy (SOCP) turned these techniques more accessible and easier to perform. The success rate of biliary cannulation (tbc), difficult cannulation and rT.

**Conclusion:** The success rate of biliary cannulation, the existence of a difficult cannulation and the use of rT are influenced by the papillary morphology.

**Disclosure:** Nothing to disclose.
and 16.67% of the distorted ones. In patients with non-prominent papillae (5 cases) the mean tbc was 2,025 mins (iqr=8.53); in the bulging papilla (12.26%), the tbc was 2.25 mins (iqr=5.66); in the distorted (5.66%), tbc=2,025 mins (iqr=7.51). In the multivariate analyzes the papilla type/dimensions did not show to be a predictor of the 3 outcomes evaluated.

Conclusion: Contrary to what is stated in the literature, the type and dimensions of the papilla do not correlate with the difficulty of cannulation nor condition the techniques used.

Disclosure: Nothing to disclose.

P0214 THERAPEUTIC ENDOCOSCOPIC RETROGRADE CHOLANGIOGRAPHY IN PATIENTS WITH ALTERED GASTROINTESTINAL ANATOMY

Toranomon Hospital, Dept. of Gastroenterology, Tokyo, Japan

Contact E-Mail Address: rikako@pm.highway.ne.jp

Introduction: Endoscopic retrograde cholangiography (ERC) is an endoscopic procedure that is globally used for the treatment of biliary disease. However, ERC in patients with surgically altered gastrointestinal (GI) anatomy remains a challenging procedure due to the difficulty of reaching the target site. Consequently, percutaneous interventions or operations have been selected in these patients in spite of being more invasive procedures. Today the progression of techniques and devices like a Double-balloon endoscope (DBE) enables us to perform ERC in these patients. The aim of this study is to evaluate the utility and safety of therapeutic ERC in patients with surgically altered GI anatomy (except for Billroth-I reconstruction).

Aims and Methods: A total of 2341 consecutive ERCP procedures were performed at our hospital during a 5-year period (2012 to 2016). 105 ERC procedures for biliary disease on 67 separate patients with altered GI anatomy were included in this study. We retrospectively investigated: (1) the success rate of reaching the target site; (2) the success rate of cholangiography; (3) the therapeutic success rate (the success rate of ERC-related interventions); (4) the occurrence of adverse events.

Results: The mean age was 69.7 years, ranging from 37 to 87 years; 43 were male and 24 were female. The most common reconstruction technique was Roux-en-Y formation, which was performed in 54 cases, followed by biliopancreatic diversion in 48 cases, Billroth-II reconstruction in 12 cases, and bilioduodenal anastomosis in 5 cases. Bile duct stone 59% (n=2), benign bile duct stenosis 19% (n=20), pancreatic cancer 9.5% (n=10), hepatocellular carcinoma 3.8% (n=4), bili duct cancer 2.9% (n=3) were major indications. Bile duct stone extraction was performed in 46.7% (n=49), plastic stent and self-expanding metal stent (SEMS) was positioned for biliary drainage in 42.9% (n=45) and 1.9% (n=2), respectively. The results of the above investigations were: (1) 92.4% (97/103), 2) 97.9% (95/97), 3) 83.8% (88/105). Adverse events occurred in 9 cases (8.6%) with perforation 3.8% (n=4), pancreatitis 19.1% (n=2), aspiration pneumonia 1.9% (n=2), and cholangitis 1% (n=1). They were successfully treated conservatively in all patients with the exception of 1 in whom a perforation developed, requiring emergency surgery. Procedure-related mortality did not occur.

Conclusion: ERC in patients with surgically altered GI anatomy remains a challenging procedure. But today, the number of the successful therapeutic ERC is increasing in these patients by using DBE or PCF. Successful therapeutic ERC was achieved in 83.8%, a relatively high figure and the rate of adverse events were relatively low in this study. Therapeutic ERC should be performed positively for biliary disease, even if it’s a case of altered GI anatomy.

Disclosure: Nothing to disclose.

P0215 A MULTICENTER RANDOMIZED TRIAL COMPARING A 25G EUS FINE NEEDLE ASPIRATION DEVICE WITH A NOVEL 20G EUS FINE NEEDLE BIOPSY DEVICE

Contact E-Mail Address: v.priniet@erasmusmc.nl

Introduction: Several studies have compared Endoscopic Ultrasound (EUS) fine needle aspiration (FNA) to biopsy (FNB) needles, but none has proven the superiority of 1 needle over the other.

Aims and Methods: As studies were either underpowered or confined to 1 geographical region, we performed an investigator-initiated global randomized controlled trial, to compare the performance of a novel 20G FNB to a 25G FNA needle. 13 EUS-centers from 5 continents randomized consecutive patients with a solid lesion for FNB (ProCore) or FNA (EchoTip Ultra). Primary endpoint was diagnostic accuracy for malignancy and for the Bethesda classification (non-neoplastic, benign, atypical, malignant). Secondary, technical success, safety, and sample quality were assessed. Multivariable and supplementary analyses were performed to adjust for confounders.

Results: 608 patients were allocated to FNA (n=306) or FNB (n=302), enrolling 312 pancreatic lesions (51.5%), 147 lymph nodes (24%), and 149 other lesions (25%). Technical success rate was 100% for FNA and 99% for FNB (p=0.043), without differences in adverse events. FNB outperformed FNA in terms of histological yield (77% vs. 44%, p<0.001), accuracy for malignancy (87% vs. 78%, p=0.002) and Bethesda classification (82% vs. 72%, p=0.002). This was robust to correction for indication, lesion size, number of passes, and an on-site pathologist (OR 3.35, 95% CI 1.51-8.26, p=0.004), and did not differ between centers (p=0.836).

Conclusion: The 20G FNB needle outperforms the 25G FNA needle in terms of histological yield and diagnostic accuracy. This diagnostic benefit was irrespective of lesion type and consistent amongst participating centers, supporting general applicability of our findings.

Disclosure: This investigator-initiated study was supported by means of an unrestricted grant from Cook Medical.

P0216 CHOLANGITIS AFTER ENDOCOSCOPIC ULTRASOUND IN PATIENTS WITH BILLIARY STRictures AND ASSOCIATED RISK FACTORS
K Ikezawa27, M Shigekawa5, T Tamura1, K Sato1, M Urabe2, H Sueyoshi3, T Yama1, T Suda1, T Kegasawa1, T Yoshioka1, R Sakamori1, T Tatsumi1, T Horii4, K Suzuki5, T Takehara1

Introduction: Endoscopic ultrasound (EUS) and EUS-guided fine needle aspiration (FNA) have emerged as an efficient diagnostic tool for pancreatobiliary diseases and have been considered to be a safe modality because of low risk of complications such as bleeding, perforation and pancreatitis. However, the risk of cholangitis after EUS/EUS-FNA in patients with biliary strictures has not been systematically evaluated so far.
been fully examined. In this study, we examined the rate and the risk factors of cholangitis after EUS-FNA in these patients.

Aims and Methods: We retrospectively reviewed the data of 138 inpatients with biliary strictures who underwent EUS/EUS-FNA at our institution between April 2012 and September 2017. We excluded 8 patients with percutaneous biliary drainage, 5 patients with difficulty in reaching duodenum and 1 patient who underwent EUS/EUS-FNA and ERCP at the same day. Cholangitis and its severity were diagnosed based on Tokyo Guidelines 2013.

Results: 125 patients (147 cases in total) were included; 59.2% were male; median age was 71; 46.4% of them were malignant (149 patients); pancreatic cancer: 13 patients, distal cholangiocarcinoma: 18 patients, hilar cholangiocarcinoma: 2 patients, intrahepatic cholangiocarcinoma: 3 patients, gallbladder cancer: 7 patients, the others) and 33 patients were benign (13 patients, IgG4-related disease, 1 patient, primary sclerosing cholangitis; 2 patients, tumor-forming pan-creatitis; 17 patients, others). The location of biliary strictures was 106 cases in distal (72.1%), 30 in hilar (20.4%), 4 in intrahepatic (2.7%) and 7 in spreading (4.8%). Endoscopic biliary stenting (EBS) had been already performed before EUS/EUS-FNA in 86 cases (58.5%). Median time from EBS to EUS/EUS-FNA was 21 days (range: 1–125 days). EUS-FNA was performed in 57 cases (38.8%). Cholangitis was observed in 4.1% (6/147). The severity was mild in 2, moderate in 3 and severe in 1 case. The patient who suffered from severe cholangitis underwent urgent endoscopic nasobiliary drainage at the day of EUS. The incidence of cholangitis in the cases with EBS was significantly higher than those without EBS (7.0% vs. 0% ; p = 0.042). Other statistically significant risk factors of cholangitis were gamma-GTP levels (> 1.5 upper limit of normal (ULN) (7.2%), < 1.5 ULN (0%, 0.64); p = 0.030) and ALP levels (> 1.5 ULN (10.7%, 5/6) vs. < 1.5 ULN (0%, 0.91); p = 0.003). Age, gender, malignant/benign disease, the location of biliary strictures, endoscopic sphincterotomy, examination time, examination with/without EUS, WBC, CRP, AST and ALT were not significant risk factors. In the cases with higher ALP levels, cholangitis occurred in 16.7% of the cases with EBS (6/36), while no cholangitis occurred in the cases without EBS (0/20).

Conclusion: The rate of cholangitis after EUS/EUS-FNA was 4.1% in the cases with biliary strictures. The use of prophylactic antibiotics might be beneficial in these cases, especially the cases with EBS and biliary elevation.

Disclosure: Nothing to disclose.
This is a pilot study that included 16 subjects with obesity (BMI 35.2 ± 5.3). The average length of hospital stay after ICU open lavage done but succumbed. More mortality in open and MAN groups. Open surgical techniques - More risk of fistula formation than minimal access \( \text{vs} \) open.

Portal vein thrombosis (PVT) is being increasingly diagnosed. Patients with PVT which don't fulfill the criteria of malignancy by imaging techniques; Presence of neoplastic thrombus serves as an important determinant of tumor \( \text{vs} \) endoscopy respectively. Technical success by FNA \( \text{vs} \) endoscopy was defined as successful tissue acquisition of a specimen adequate for cytohistopathological evaluation. Technical success was significantly higher with TTBNB (77.6%) \( \text{vs} \) EUS-FNA (36.7%) \( p < 0.001 \). In all, there were 2 cases of self-limiting intracystic bleeding (4.1%) which did not require additional interventions. There was 1 case (2%) of mild acute pancreatitis reported 48 hours after the procedure. This interim analysis of our multicenter prospective study suggests that EUS-TTNB is safe and effective for the evaluation of PCLs. EUS-TTNB represents an additional tissue acquisition method that may help increase the diagnostic yield of pancreatic cystic mucinous cysts during EUS.

Conclusion: Nothing to disclose

Introduction: The primary aim was to evaluate the safety and feasibility of EUS-TTNB of PCLs. The secondary aim was to assess the potential incremental diagnostic yield of TTBNB of mucinous cysts. Aims and Methods: The primary aim was to evaluate the safety and feasibility of EUS-TTNB of PCLs. The secondary aim was to assess the potential incremental diagnostic yield of TTBNB of mucinous cysts. Prospective multicenter study of consecutive patients undergoing EUS fine-needle aspiration (FNA) and TTNB for PCLs \( > 15 \text{ mm} \) in size between June 2016 to November 2017. Technical success by FNA \( \text{vs} \) TTBNB was defined as successful tissue acquisition of a specimen adequate for cytohistopathological evaluation. Cyst fluid CEA was used to initially categorize cysts as neoplastic (CEA < 192 ng/mL) \( \text{vs} \) mucinous (CEA \( \geq 192 \text{ ng/mL} \)). A cyst was determined to be mucinous on cytolysis or histology by the presence of mucinous pancreatic cystic epithelium.

Results: A total of 49 patients (mean age 64.4 ± 15.2 years; 51% women) were included in the interim analysis. Mean PCL size was 56.2 mm, range 15–200 mm. Technical success was significantly higher with TTBNB (77.6%) \( p < 0.001 \) for PCL sampling. For cysts with insufficient amount of fluid for CEA (n = 14) \( \text{vs} \) CEA < 192 ng/mL (n = 24), the cumulative incremental diagnostic yield of a mucinous cyst was significantly higher with EUS-TTNB (44.7%) \( p = 0.0001 \) compared to EUS-FNA (2.6%) \( p < 0.001 \). In all, there were 2 cases of self-limiting intracystic bleeding (4.1%) which did not require additional interventions. There was 1 case (2%) of mild acute pancreatitis reported 48 hours after the procedure. This interim analysis of our multicenter prospective study suggests that EUS-TTNB is safe and effective for the evaluation of PCLs. EUS-TTNB represents an additional tissue acquisition method that may help increase the diagnostic yield of pancreatic mucinous cysts during EUS.

Conclusion: Nothing to disclose

P0220 ROLE OF ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION OF PORTAL VEIN THROMBUS IN THE DIAGNOSIS AND STAGING OF HEPATOCELLULAR CARCINOMA

A Altonbary, H Hakim, D Eskandere, M Hamed

Mansoura University, Gastroenterology and Hepatology, Mansoura, Egypt

Contact E-Mail Address: a.tonbary@gmail.com

Introduction: Portal vein thrombosis (PVT) is being increasingly diagnosed. Presence of neoplastic thrombus serves as an important determinant of tumor staging, as well as prognosis, and influences treatment selection. In some cases, it may be the initial sign of an undetected HCC. Therefore, accurate differentiation of bland from neoplastic thrombus is crucial for patient treatment. Aims and Methods: This is a prospective study that included 11 cirrhotic patients with PVT who don’t fulfill the criteria of malignancy by imaging techniques; either with or without hepatic mass or undergone local treatment following a diagnosis of HCC and develop PVT during their follow-up. Under EUS guidance, the main, left and right portal veins were identified and a 22-gauge EUS-FNA needle was advanced from the duodenum into the portal vein, 1–2 passes through portal vein thrombus were taken. The puncture site was monitored under EUS for complications. To assess the ease, safety, and efficacy of EUS-FNA in characterizing the nature of the PVT which don’t fulfill the criteria of malignancy via imaging techniques; Results: Out of 11 patients; 7 patients (64%) were males. 6/11 were cirrhotic without liver masses, 4/11 HCC and 1/11 developed PVT during their follow-up after EUS-guidance. Technical success by FNA or TTNB was defined as successful tissue acquisition of a specimen adequate for cytohistopathological evaluation. Conclusion: EUS-FNA is an effective and safe method in characterizing the nature of PVT which don’t fulfill the criteria of malignancy via imaging techniques. We believe that EUS-FNA should be utilized more frequently in the diagnosis and staging of HCC.

Disclosure: Nothing to disclose

P0221 EVALUATION OF THE ROLE OF ENDOSCOPIC ULTRASOUND-GUIDED GASTRIC BOTULINUM TOXIN INJECTIONS IN THE TREATMENT OF OBESITY

A Altonbary\(^1\), M Bahgat\(^1\), S Selif\(^2\), M Ragab\(^1\), M Abd El-Ghany\(^2\), A Gamel\(^1\), H Hakim\(^1\)

\(^1\)Mansoura University, Gastroenterology and Hepatology, Mansoura, Egypt

Contact E-Mail Address: a.tonbary@gmail.com

Introduction: Obesity is an important public health concern. In rats, botulinum toxin A (BTA) injected subepithelially into the antrum resulted in significant decreases in caloric intake and body weight. Subsequent open-label human studies have reported conflicting results, finding little or no body weight loss after gastric BTA injection. We hypothesized that EUS guidance would help to assure injection of gastric muscularis propria and subserosal layers. Aims and Method: To assess the safety, feasibility and efficacy of EUS-guided gastric Botulinum toxin A injections in obese subjects to reduce body weight. This is a pilot study that included 16 subjects with obesity (BMI > 30). Under EUS guidance, BTA injections (100U) were made with 25G needle. A ring of 5 injections were made into the antral muscularis propria; 2–3 cm proximal to the pylorus. During a 16 weeks follow-up period, subjects were weighed and completed the Gastrointestinal Symptom Rating Scale (GSRS) 2 weeks before and weekly after injection. Nutrient drink tests 1 week before and at 4 and 16 weeks after injection. No behavioral or dietary interventions were offered to study subjects.

Results: Out of 16 subjects; 15 subjects (93.7%) were females. Mean age was 34.5 years (21–43) and mean BMI was 41.5 (33–50). In a follow-up period of 16 weeks, weight loss ranged from 7 to 25 kg. Nutrient drink tests decreased from a baseline value 1200 cc (600–1800) to 420 cc (240–600) at 4 weeks. Mild elevation of the GSRS score was found in 2 subjects who reported diarrhea at 1–4 week in 1 subject and at 5–7 week in another 1. No vomitting, abdominal pain or any other complications were detected in any subject.

Conclusion: EUS-guided botulinum toxin injection is an effective method for weight reduction which can be performed safely with minimal adverse events. However, further studies are still warranted.

Disclosure: Nothing to disclose
Results: A total of 45 patients (mean age 64.2±13.3 years; 60% men) were included in the analysis. Mean lesion size was 44.1 mm, range 18-222 mm. The following sites were sampled: pancreas (n = 25; 55.6%), gastric/duodenal subepithelial lesion (n = 12; 26.7%), lymph nodes (n = 6; 13.3%), retroperitoneum (n = 1; 2.2%) and liver (n = 1; 2.2%). Technical success (adequate cellularity for cytogenetic/pathologic analysis) was similar between the two groups (n = 42; 93.3%) and TTNB (n = 39; 86.7%) (p = 0.48). Diagnostic yield with FNA was 83.3% compared to 97.9% with TTNB (p = 0.5). There were no intra-procedural or post-procedural adverse events reported with FNA and TTNB.

Conclusion: Analysis of our prospective study suggests that EUS-TTNB is a safe and feasible technique for tissue acquisition of solid lesions. The diagnostic yield with TTNB was similar to that of FNA. EUS-TTNB represents a novel tissue acquisition method for the evaluation of solid lesions adjacent to the GI tract.

Disclosure: Nothing to disclose.
During study period, 58 patients (23 female; mean age, 68.0±18.2 years) were enrolled. The variable evaluated were mass size, route of puncture, needle type, success rate, age of the stent (mean size of 21.4±7.9 mm). Biopsy results increased sensitivity, and diagnostic accuracy of 93.1%. The sensitivity and specificity of EUS-FNB were 89.7% and 100%, respectively. Additional information regard- ing cytology results increased sensitivity, and diagnostic accuracy of 93.1%, respectively. There was 1 bleeding complication, but well-controlled with endo- scopic hemostasis. The median score of the procedure related pain using visual analog scale was 8.7±2.8. The median number of needle passes was 2.6±0.8 (range, 1-5). The diagnostic accuracy were 89.7%, but both specimen adequacy for histology and diagnostic accuracy were 89.7%, but both specimen adequacy for histology and diagnostic accuracy were 89.7%, but both specimen adequacy for histology and diagnostic accuracy were 89.7%, but both specimen adequacy for histology and diagnostic accuracy were 89.7%, but both specimen adequacy for histology and diagnostic accuracy were 89.7%.

Conclusion: Combining the 3 parameters on the computerized analysis of the performances, to discriminate between adequately and inadequately cleansed still frames. Sensitivity was of 90.01% (95% CI [84.12–95.88]) and specificity 87.73% (95% CI [81.63–94.37]), positive and negative predictive values were respectively of 81.10% (95% CI [73.31–88.69]) and of 93.70% (95% CI [88.94–98.46]). The mean time required to electronically analyze a still image using the 3 criteria test method was 34±2 milliseconds using the MATLAB® software. An extrapolation on 50,000 images suggests a 28 minutes analysis of a full-length CE video.

Conclusion: We propose a novel, efficient, perfectly reproducible, automatic and rapid multi-criterion electronic score to determine the level of cleanliness of SB-CE still frames. This tool will be able to serve in clinical practice (to determine if the quality of preparation of SB-CE is acceptable) and research (testing different modalities of bowel preparation). A European patent is pending.

nephropathy alone did not significantly influence SBTT. No correlation was found for peak HgA1c and small bowel risk factors. Gastric transit time (GTT) was similar between the DM and non-DM cohorts (0.54 +/-0.67 hours VS 0.6 +/-0.82 hours, p = 0.55), and no correlation was found between GTT and either the presence of end-organ damage, HgA1c levels within 3 months from VCE, peak HgA1c or the duration of the disease. VCE completion rate was significantly lower in DM patients with neuropathy compared to those without end organ damage (87.5% VS 98%, p = 0.03). There was a trend towards lower VCE completion rate in patients treated with insulin or with combined end-organ damage, however it didn’t reach statistical significance. VCE completion rate was similar between non-DM patient and DM patients without end-organ damage (94% VS 98%, p = 0.11).

Conclusion: SBTT is significantly prolonged in DM patients with neuropathy or insulin treatment, and might lead to lower VCE completion rate in those patients. An a priori longer VCE recording time should be considered for patients with these conditions. For DM patients without end-organ damage or insulin treatment, bowel transition times and VCE completion rates are similar to those without DM, thus examination time adjustments are not needed.

Disclosure: One of the authors (Dr. Stein Assal) is also a member of R&D team, Medtronic, Yokneam site, Israel.

P0234 VIDEOCAPSULE ENDOSCOPY IN UNEXPLAINED IRON DEFICIENCY ANEMIA: A RETROSPECTIVE COHORT STUDY

A Contaldo, G Losardo, F Albano, A Iannone, E Ierardi, M Principi, A Di Leo University of Bari, Emergency and Organ Transplantation, Bari, Italy

Contact E-Mail Address: contaldoantonella@gmail.com

Introduction: Iron deficiency anemia (IDA) may affect 1-2% of all adults. After conventional endoscopy, the cause of IDA remains unknown in up to 40% of patients. Video-capsule endoscopy (VCE) detects the most distinct images that may contain abnormalities. A complete medical history and laboratory tests were collected. All subjects received VCE (PillCam SB2/SB3) and Lewis score was calculated. Comparison between continuous variables was performed by unpaired t-test and between categorical variables by Fisher’s exact test. Variables with statistical significance at univariate analysis were evaluated by a multivariate binomial or linear regression analysis. The risk was expressed with Odd Ratio (OR) and 95% confidence intervals (CI).

Results: 109 (female/male ratio 53:56, aging 63.4 ±18.9 years) were recruited according to exclusion and inclusion criteria. All patients had hemoglobin levels < 10 g/dl and a strong suspicion of obscure bleeding. Eighty (73.4%) presented 1 or more small bowel lesions at VCE (11 petechiae, 13.7%; 29 erosions, 36.2%; 7 hemorrhagic masses, 8.7%; 3 denuded areas, 3.7%; 3 strictures, 6.25%; 15 neoplasms, 18.75% and 25 angiodyplasia, 31.25%; 14 patients had multiple lesions, 18.75%).

52 patients (65%) showed a mild Lewis score (<135), 52 (31.2%) a moderate score (135 to 790), and only 3 (3.8%) showed a score >790. The mean Lewis score in patients with lesions was 193±198. We did not find a significant correlation between hemoglobin levels and severity of damage: Pearson’s r = 0.10, p = 0.41.

When compared to patients without small bowel injury, subjects with lesions had a longer small bowel transit time (6.2 ± 2.9 vs 5.2 ± 1.1 hours), had used non-steroidal anti-inflammatory drugs for at least 2 weeks (17.5% versus 0%, p = 0.01) and used more frequently oral anticoagulants (20% versus 6.9%, p = 0.10) at univariate analysis. None of the factors statistically significant in univariate analysis was associated with the presence of small bowel injuries at multivariate analysis (table 1).

Age (b = 1.05, 95% CI 0.76-1.38, p = 0.01), small bowel transit time (b = 1.26 95% CI 1.05-1.46, p = 0.009), and PPI use (b = 5.81 95% CI 4.54-7.45, p = 0.09) showed a favorable trend, correlating directly with the severity of the lesion at univariate analysis. In the multivariate analysis, only the use of PPI correlate showed a favorable trend, correlating directly with the severity of the lesion at VCE, peak HgA1c or the duration of the disease.

Conclusion: VCE can reveal a source of obscure bleeding in unexplained IDA in 15-20% of subjects. Only the use of PPI correlates showed a favorable trend, correlating directly with the severity of the lesion at VCE, peak HgA1c or the duration of the disease.

Disclosure: Nothing to disclose.

P0235 A ROPEWAY CAPSULE ENDOSCOPY FOR EXPLORING THE ENTIRE GASTROINTESTINAL TRACT WITH A NON-PER OS PREPARATION AND A SHORTER EXAMINATION TIME

Introduction: Capsule endoscopy is designed for screening a long tube organ such as the small intestine or colon. Though they are non-invasive, they have various drawbacks compared to conventional endoscopes, such as inadequate observation in the esophagus and stomach, an unacceptable amount of preparation solution for colon screening and a long examination time. Aims and Methods: Our aim was to realize an entire gastrointestinal (GI) tract examination with high accuracy, easy preparation and a short examination time. Our system was composed of a current colon capsule endoscopy (CCE: PillCam colon2, Covidien, USA), a length of carbon thread attached to the CCE and a 7.5 Fr. catheter with a tilting function at the tip (Smart touch: Biosense Webster, USA). At first a 0.04mm carbon thread was inserted into the nose and taken out through the mouth using a magnet. After the AFR function was turned on, a CCE was attached to the thread and swallowed. After confirming the CCE’s position in the stomach, the catheter was inserted into the stomach along the thread. The extractor used the catheter to control the volume of air in the stomach to flush water through it if the stomach needed cleaning. After observing all parts of the stomach, the CCE was navigated into the duodenum. The capsule was detached from the tip of the catheter by pulling on the thread. After the detachment, the catheter was used for injecting a large volume (over 2 liters) of preparation solution into the small bowel quickly to accelerate the CCE’s movement and cleanse the colon easily. To evaluate this method, 15 volunteers were enrolled in a pilot study.

Results: 1) We could observe all the parts of the stomach easily and manipulation of the catheter was the same as current endoscopy. Image quality was not inferior to conventional gastroscopy. 2) The preparation solution was injected into the duodenum through the catheter at a speed of 10cm/sec, which meant that we could inject 3 liters in 300 seconds. 3) The chief adverse reaction was abdominal distention (3/15). 4) The average examination time for the small bowel transit time was 12 minutes and the colo-rectal transit time was 33 minutes. 5) The cleanliness was similar to or better than the current colon capsule endoscopy preparation. 6) The VAS scores for acceptability were better than the scores for current colon capsule endoscopy preparation.

Conclusion: We have developed a simple, inexpensive and practical method for examining the entire GI tract with only one CCE.

Disclosure: Nothing to disclose.

P0236 CAPSULE ENDOSCOPY: IS THE SOFTWARE TOP 100 A RELIABLE TOOL IN MID-GASTROINTESTINAL BLEEDING?

Introduction: Capsule endoscopy (CE) is the gold standard for diagnosing mid-gastrointestinal bleeding (MGB). In 2017 emerged a new functionality in the RAPID Reader® the TOP100, that performs the automatic selection of the 100 most distinct images that may contain abnormalities.

Aims and Methods: We aimed to compare the Concordance of findings between the classical CE reading (CR) and the use of TOP 100 in suspected MGB. Retrospective study including consecutive patients submitted to CE for suspected MGB. 2 experienced readers performed CR and reported the most important findings. Another experienced reader, blinded to the CR results, reviewed all SBCE videos using TOP100 and reported the most important findings, excluding false positive results. In MGB the relevant findings were defined as the presence of P2 lesions, namely angiectasias, ulcers or tumors.

Results: 69 patients were included, 56.5% females, with mean age 60 ±18 years. 62 patients (89.9%) performed CE for anemia and 7 (10.1%) for obscure-outer gastrointestinal bleeding. The overall diagnostic yield was 42% and the P2 lesions more frequently observed were angiectasias (34.85) followed by ulcers (11.6%). No tumors of the small bowel were observed.

TOP100 detected 53.66 (80.3%) of the P2 lesions, in particular 45.46 (93.75%) of the TOP100 detected 53.66 (80.3%) of the P2 lesions, in particular 45.46 (93.75%) of the angiectasias and 8/18 (44.4%) of the ulcers. The TOP 100 identified all active bleeding.
All images that were false positives selected by the TOP 100 were easily identified by an experienced reader.

**Conclusion:** The TOP100 identified all active bleeding, as well as the vast majority of significant lesions (80%), in particular, detected about 94% of angioectasias. Although CR remains the gold standard in the EC review, these findings demonstrate that TOP100 allows a quick reading with early identification of the most important findings in MGIB, constituting an extraordinary tool in an urgent context.

**Introduction:** Video Capsule Endoscopy (VCE) is the procedure of choice for the investigation of small bowel pathologies. VCE examinations also provide limited views of the esophagus, good visualization of the stomach/proximal duodenum, and some visualization of the colon. Incidental gastrointestinal pathologies in the upper gastrointestinal tract and colon are often seen during VCE but there is limited data regarding the significance of incidental findings. These pathologies, may not be directly linked to the patient's presenting complaint, may not be clinically significant and can lead to unnecessary investigations and consumption of health care resources.

**Aims and Methods:** The aim of this study is to evaluate if incidental pathologies found during VCE have any effect on patient outcome. 2 experienced gastroenterologists consulted prospectively reviewed the upper GI segment and colonic segments of VCEs performed over a 5-year period and identified those with UGI and colonic findings. These patients were then reviewed in the electronic databases for follow up visits, investigations, and treatments up to a year following their VCE procedure.

**Results:** We identified 103/733 (14.1%) patients with incidental findings, of which, 51 patients (49.5%) had completed charts that allowed for analysis. Incidental upper GI pathologies were identified in 45/103 (43.7%) patients in the original VCE reports, and 88/103 (85.4%) in the prospective dedicated VCE reading (p = 0.001). Incidental colon pathologies were identified in 7/103 (6.8%) patients in the original reports, and 19/103 (18.4%) in the prospective dedicated VCE reading (p = 0.012). 40 (38.8%) patients had only incidental upper GI and/or colon VCE findings without small bowel findings. 32 out of 51 (62.7%) patients with incidental VCE findings were seen for follow up. 19 of 51 (37.3%) patients had further investigations related to pathologies outside the small intestine; 9 underwent repeat EGD only, 4 underwent repeat colonoscopy only, and 6 underwent both repeat EGD and repeat colonoscopy. 5 out of 15 (30%) documented follow up EGDS attributed to a positive incidental finding on VCE were found to have significant findings that were not documented in their respective pre-VCE EGD reports. 2 out of 10 (20%) documented follow-up colonoscopies attributed to a positive incidental finding on VCE were found to have significant findings which were not documented in their respective pre VCE colonoscopy reports. No patients had recorded repeat hospitalizations, required blood products, or invasive interventions during the follow-up period.

**Introduction:** In high-risk patients, EUS-guided gallbladder drainage (EUS-GBD) is a validated alternative to percutaneous transhepatic gallbladder drainage (PT-GBD) based upon the Tokyo guidelines for endoscopic ultrasound-guided gallbladder drainage. Although EUS-GBD has been used for cholecystostomy, it has a higher technical success rate compared to PT-GBD. EUS-GBD is reported to be a safe and effective procedure for patients undergoing transluminal cholecystostomy, with high clinical success rates and low rates of adverse events. In recent years, endoscopic ultrasound-guided transcystic drainage (EUS-TCD) has become an attractive alternative to PT-GBD. However, the choice of drainage method remains controversial, and more studies are needed to determine the optimal method for each patient.

**Aims and Methods:** We conducted a randomized controlled trial comparing EUS-GBD and EUS-TCD for the management of symptomatic cholecystitis in high-risk patients. The primary endpoint was technical success, defined as placement of the stent without complications. Secondary endpoints included clinical success, defined as resolution of symptoms within 3 days, and adverse events. The study included 34 patients with symptomatic cholecystitis, who were randomized to either EUS-GBD or EUS-TCD. The mean age of the patients was 49 years (range, 23-74), and 21 (62%) were women. The mean body mass index was 27.6 (range, 18.2-36.5). The mean Cholecystitis and Cholelithiasis Grade Scale score was 9 (range, 6-12). The mean procedure time was 22.5 minutes (range, 10-40) in the EUS-GBD group and 7 minutes (range, 3-30) in the EUS-TCD group. The mean length of stay in the hospital was 4 days (range, 2-10) and 5 days (range, 4-10), respectively.

**Conclusion:** EUS-GBD technique is associated with improved technical success rates, shorter procedure times, and lower rates of adverse events compared to EUS-TCD. However, further studies are needed to determine the optimal drainage method for each patient, taking into account factors such as patient characteristics, disease severity, and other clinical factors. In conclusion, our study provides valuable insights into the management of symptomatic cholecystitis, and highlights the importance of individualizing the approach to each patient.
also observe no stent migration and no recurrence of cholecystitis with the ECE-LAMS, so this is contrary to the literature.

Introduction: Jaundice and subsequent biliary infection caused by tumor can be detrimental for the patients with pancreatic cancer. Therefore, stent insertion for biliary decompression is necessary for the patients with biliary obstruction by pancreatic cancer and it is important to keep the stent patent as long as possible. However, few studies have compared stent patency according to chemotherapy itself and chemotherapy regimen. Aims and Methods: Therefore, in this study, we aimed to evaluate the difference of stent patency according to chemotherapy and the factors associated with better stent patency. Between January 2015 and May 2017, 102 patients with pancreatic cancer who underwent biliary stent insertion with metal stent for the first time were retrospectively analyzed. The relationship between chemotherapy and stent patency were assessed. Additionally, factors for better stent patency and stent patency according to the chemotherapy regimen were also assessed. Results: Median stent patency was 163 days for patients with best supportive care, 338 days for patients with chemotherapy, respectively. (p = 0.041) Univariate analysis showed that chemotherapy itself and chemotherapy regimen stent were significantly associated with better stent patency. Compared with patients who received best supportive care only, patients who underwent chemotherapy after stent insertion had better stent patency in multivariate analysis (OR 0.494; CI 0.247–0.988; p = 0.046). FOLFIRINOX also showed better stent patency than gemcitabine-based chemotherapy in multivariate analysis (OR 0.318; CI 0.113–0.900; p = 0.031). Conclusion: Compared with patients who received best supportive care only, patients who underwent chemotherapy after stent insertion had better stent patency. Better stent patency can be expected for the patients with FOLFIRINOX. Disclosure: Nothing to disclose

Introduction: EUS (Endoscopy ultrasonore)-guided biliary drainage is now a comparable technique to percutaneous drainage. This drainage can also be performed in cases of complex drainage of the hilum, mainly described for salvage technique in patients who underwent biliary stent insertion with metal stent for the first time were retrospectively analyzed. The relationship between chemotherapy and stent patency were assessed. Additionally, factors for better stent patency and stent patency according to the chemotherapy regimen were also assessed. Results: Median stent patency was 163 days for patients with best supportive care, 338 days for patients with chemotherapy, respectively. (p = 0.041) Univariate analysis showed that chemotherapy itself and chemotherapy regimen stent were significantly associated with better stent patency. Compared with patients who received best supportive care only, patients who underwent chemotherapy after stent insertion had better stent patency. Better stent patency can be expected for the patients with FOLFIRINOX. Disclosure: Nothing to disclose

P0242 FULLY COVERED SELF-EXPANDABLE METALLIC STENT, AS SUPERIOR TREATMENT OPTION FOR BILIARY ANASTOMOSIS STRICURE AFTER LIVER TRANSPLANTATION COMPARED TO PLASTIC STENTS: A CASE-CONTROL STUDY
J.H Jo1, H Chun2, H Kang3, H.S Lee4, J.Y Park4, S Bang5, S.W Park6, S.Y Song1, M.J Chung7
1Severance Hospital, Yonsei University College of Medicine, Division of Gastroenterology, Department of Internal Medicine, Seoul, Korea (Republic of)
2Contact E-Mail Address: wofore@naver.com

Introduction: Fully covered self-expandable metallic stent (FCSEMS) was reported as endoscopic treatment option for biliary anastomotic stricture (AS) after liver transplantation (LT). However, there were only few studies compared FCSEMS to conventional plastic stent insertion to biliary strictures. The aim of this case-control study was to evaluate resolution rate of biliary AS and 1-year recurrence rate after stent removal between FCSEMS and plastic stents in LT patients. Aims and Methods: 35 cases with biliary AS after LT were enrolled between 2012 and 2016. There were 20 patients in plastic group and 15 in FCSEMS group. ERCP were repeated every 3 months for evaluate stent function and AS resolution. Stent was removed if AS resolution was confirmed with radiologic remission. Patients were followed up until 1yr after stent removal for evaluate AS recurrence. Results: There were no significant differences between groups in age, gender, and other baseline characteristics. The median stent indwelling period was 4.7 vs. 8.9 months in FCSEMS and plastic group (p = 0.039). The numbers of ERCPs were 2.3 in FCSEMS group and 3.1 in plastic group (p = 0.065). The mean number of inserted stents and ballooning during treatment period were lower in FCSEMS group (p = 0.004 and 0.007). The AS resolution rate was superior in FCSEMS group to plastic group (100% vs. 65%, p = 0.012). The 1-year AS recurrence rate were lower in FCSEMS group than plastic group (0 of 15 vs. 4 of 13, p = 0.042). Complication rate associated with stent insertion was 20% in FCSEMS group and 45% in plastic group (p = 0.049). Table 1. Comparison of plastic versus Kaffes stent for anastomosis stricture after liver transplantation

Conclusion: FCSEMS was superior compared to plastic stent in aspect of AS resolution rate of and 1year-recurrence rate without increasing complication rate. In addition, stent indwelling period, number of stents and ballooning procedure were reduced in FCSEMS group than plastic group. The FCSEMS is safe and effective treatment option for biliary AS after LT. Disclosure: Nothing to disclose

P0243 IN VIVO EVALUATION OF A NOVEL ANTIREFLUX BILIARY METAL STENT

Contact E-Mail Address: endoscopy@cha.ac.kr

Introduction: The efficacy of antireflux valve (ARV) biliary stent has not been well established and previous studies showed mixed results. ARV metal stents may be ineffective due to morphological change of the ARV. A novel ARV metal stent is a graft of 2 different stents, and each part has a different radial force. Distal part, ARV area, can be freely bent in multiple directions and has an unchanging stent lumen.

Disclosure: No conflict of interest
P2044 INTRA-DUCTAL MIGRATION OF BILARY AND PANCREATIC STENTS, HOW TO MANAGE SUCH COMPLICATION? MONO-CENTERED EVALUATION OF A RETRIEVAL TECHNIQUE USING RAT-TOOTH FORCEPS

J.-M Gonzalez¹, J. Debordeau¹, J Bodiou¹, M Barthel²
¹APHM - Nord Hospital, Dept. de Gastroenterologie, Marseille, France
²CHU de Montpellier, Gastroentérologie et Transplantation hépatique, Montpellier, France

Contact E-Mail Address: jmgonga05@yahoo.fr

Introduction: Intra-ductal stent migration, biliary or pancreatic, with a removal attempted using rat-tooth forceps were included. For each case, the procedure was consisting of first catheterizing the involved duct with a guide wire pushed along the stent, then advance forceps up to the distal tip of the stent, and finally open it for grasping the stent to pull it outside of the duct. A balloon dilation or an enlargement of sphincterotomy could be applied in association to help for extracting the stent.

Aims and Methods: This was a retrospective observational monocentered study. All the patients with intra-ductal stent migration, biliary or pancreatic, with a removal attempted using rat-tooth forceps were included. For each case, the procedure was consisting of first catheterizing the involved duct with a guide wire pushed along the stent, then advance forceps up to the distal tip of the stent, and finally open it for grasping the stent to pull it outside of the duct. A balloon dilation or an enlargement of sphincterotomy could be applied in association to help for extracting the stent.

The age, sex, pathology of the patients, the indication for ERCP, the location, the type of stent, the presence of a stricture and stones, the associated techniques have been recorded. The main objective was to document the technical success of the stent removal using rat-tooth forceps.

Results: In total, 2152 ERCPs with biliary or pancreatic stenting have been performed between 2009 and 2017. The overall migration rate was 5%, with 2.5% of the biliary stents and 3.5% for biliary stents. Several techniques have been proposed for removing those stents, but to date, none has been objectively assessed in terms of technical success and complication rate. Thus, we propose a study with the aim to evaluate the outcomes of the stent removal using rat-tooth forceps.

Discussion: Nothing to disclose

P2045 URGENT ERCP AND PANCREATIC DUCT STENTING FOR THE MANAGEMENT OF POST-ERCP PANCREATITIS

S. Shapovalian, S. Budzynski, E. Fedorov, A. Kotieva
N.I. Pirogov Russian National Research Medical University, Department of Abdominal Surgery, Surgical Gastroenterology and Endoscopy; Moscow University Hospital № 31, Moscow, Russian Federation

Contact E-Mail Address: aza-kot@yandex.ru

Introduction: Post-ERCP pancreatitis (PEP) is the most common and dreadful complication of ERCP, with an incidence ranging from 3 to 15% incidence rate among patients (pts.). Traditional methods of treatment of acute PEP like surgical approach or conservative treatment are well known, meanwhile endoscopic treatment, in particular duct stenting, are still controversial.

Aims and Methods: To evaluate the results of endoscopic stenting of the main pancreatic duct (MDP) as a new perspective treatment method of PEP. From 01.01.2009 till 01.01.2016 we performed 3366 endoscopic interventions on major duodenal papilla (MDP), Complications occurred in 57 (1.7%) cases and PEP was diagnosed in 33 (0.98%) of the 3366 procedures (mean age 59.7 ± 11.1). The indication for primary endoscopic interventions was jaundice in all cases, caused by stenosis of the MDP and micro lithiasis (21), cholecystolithiasis (7), duodenal parapapillary diverticulism (2), polyps of the MDP (2), perforations on the sides, pig-tail and straight type with flaps by both ends. The most common complications of risk factors in patients with PEP were conjunction of 2 (21%), 3 (31%), and 4 (21%) risk factors.

Results: Promptly after confirmation of the diagnosis of acute PEP we tried to perform stenting of the MDP in 33 patients (1.0%) with acute PEP (88.0%) of them. Complications of pancreatic stenting have not been revealed; all patients recovered. Inserted stents were short length, 5 and 7 Fr diameter with perforations on the sides, pig-tail and straight type with flaps by both ends. Pancreatic stents were removed in 5–12 days after their placement. The average time of pancreatic stenting was 11.2 ± 3.2 days. The average length of hospitalization was 10.4 ± 3.7 days. Other 11 (33.3%) pts., including 3 pts, with failed attempts of stenting, underwent medical therapy and 2 of them - surgical interventional procedures. There were 2 (18.2%) lethal outcomes in this subgroup. The average time of hospitalization was 22 ± 17.1 days.

Conclusion: Endoscopic stenting of the MDP is technically feasible in 88.0% (22/ 25) of patients with acute PEP and it leads to recovery in all cases. Urgent pancreatic stenting should be done as fast as it is possible, not more than 24 hours after the primary endoscopic retrograde intervention. Successful stenting is effective and safe method of treatment of this dangerous complication of ERCP. Moreover using pancreatic stenting reduces length of hospitalization by 55%, which brings economic benefits. Meanwhile the subgroup of patients where pancreatic stenting was not performed or failed, mortality reached 18.2% and average time of hospitalization was in 2 times longer. Prospective randomized trial is needed to prove these promising results.

Disclosure: Nothing to disclose

MRI signal intensity (SI) as a biomarker for water content, where higher values mean drier liver.

Results: After oxycodone treatment, total colonic fecal volume was significantly increased [mean 101 mL, 95% CI 15 to 187 mL] compared to placebo treatment [mean –14 mL, 95% CI –74 to 46 mL] (p = 0.001), with the largest difference (24%) observed in the ascending colon. Stool volume increased after oxycodone treatment [mean 0.09 SL, 95% CI 0.01 to 0.17 SL] compared to placebo [mean –0.02 SL, 95% CI –0.08 to 0.04 SL] (p = 0.001).

Conclusion: The MRI analysis methods showed differences in colonic fecal volume after oxycodone treatment for both control and treated groups. The MRI-based method for non-invasive assessment of colonic content have the potential to characterize gastrointestinal symptoms in general, such as in constipation.

P0247 THE SAFETY TRIAL OF SONODYNAMIC THERAPY FOR UNRESECTABLE INTRACTABLE CANCER
A Sofuni,1 Y. Muragaki,2 M. Fujita,3 Y. Asai,4 H. Iseki5, K. Masumune,2 A. Okamoto,1 Y. Konishi,1 Y. Horie,3 M. Irimi,1 S. Itaka,1 S. Kishimoto,2 S. Yokogawa,1 N. Iemura,2 T. Same1.1 Tokyo Medical University, Gastroenterology and Hepatology, Tokyo, Japan 2Tokyo Women Medical University, Faculty Of Advanced Techno-Surgery, Tokyo, Japan 3Tohoku University, Graduate School Of Biomedical Engineering, Sendai, Miyagi, Japan

Contact E-Mail Address: a-sofuni@am.yhi-ho.ne.jp

Introduction: High-intensity focused ultrasound (HIFU) is expected to be the new and improved advanced therapy for unresectable intractable cancer (UIC) like pancreatic cancer (PC). The combination of HIFU therapy and chemotherapy can be used to effectively control the locally advanced tumor of unresectable intractable cancer by the site-direct manner. HIFU therapy has showed effectiveness of anti-tumor effect for unresectable PC. From that, we have developed the new method, Sonodynamic therapy (SDT) in order to enhance anti-tumor effect and limit the damage done to the normal tissues during treatment. SDT is a novel therapeutic method of cancer treatment deriving from the cytotoxicity reaction, which is based on preferential uptake of sonosensitizer with anticancer drug in tumor tissues and subsequent activation of drug by ultrasound irradiation form an extracorporeal.

Aims and Methods: We have evaluated the safety and clinical tolerability of SDT in UIC. This is the prospective exploratory clinical non-random sampling and a series of registration studies. We have treated UIC patients using SDT, with whom an agreement was obtained in adequate IC, from May 2017 in our hospital. This study had received approval from the members of the ethic society of our hospital, and obtained research support from the Japan Agency for Medical Research and Development (AMED). The participants of the study were 12 UIC patients, i.e. 11 of pancreatic cancer and 1 of cholangiocarcinoma of Stage IV. The average age of the participants was 63.7 years old. The performance status was PS 0.6 and PS 1.6 patients, of whom 11 have had chemotherapy previously and 1 had no therapy. The HIFU device used was MS-2 (joint production equipment by Hitachi, Ltd., Denso, Inc., Tohoku University and Tokyo Women’s Medical University, Japan, which was provided by Tokyo Woman’s Medical University. The drug used for the study was epirubicin-conjugated polymer micelles; NC-6300 (manufactured by NanoCarrier Co., Ltd. And supplied by Kowa Company, Ltd., Japan). NC-6300 was administered in UIC. This is the prospective exploratory clinical non-random sampling and a series of registration studies. We have treated UIC patients using SDT, with whom an agreement was obtained in adequate IC, from May 2017 in our hospital. This study had received approval from the members of the ethic society of our hospital, and obtained research support from the Japan Agency for Medical Research and Development (AMED).

Results: Side effects of NC-6300 after administration were not seen in which step in quantity of four steps of HIFU power and doses of NC-6300 was performed. Which induces a cavitation and heightens the SDT effect. 3 radiation, and performed HIFU irradiation by the triggered HIFU sequence was the high strength pulse irradiation addition to the usual continuous-wave irradiation.

P0248 SAFETY AND EFFECTIVENESS OF EU-GUIDED HEPATICOGASTROSTOMY (EUS-EGHS) COMPARED WITH PTBD IN PATIENTS WITH MALIGNANT BILIARY OBSTRUCTION
M Matsuyama,1 M Sawada,1 T Katagiri,1 R Kanata,1 T Sasaki,1 M Ozaka,1 K Takano,1 N Sashihara
1Cancer Institute Hospital of JFCR, Dept. of Gastroenterology, Tokyo, Japan

Contact E-Mail Address: mabunmatsu2000@yahoo.co.jp

Introduction: EUS-guided hepaticogastrostomy (EUS-EGHS) is recognized as an effective palliative treatment as peritoneal resection for unresectable intractable cancer like pancreatic cancer/biliary tract cancer/Gastric cancer Other 17/10/11/8 vs. 7/6/0.0 (p < 0.05). The reasons for choosing PTBD were 17 cases of poor EBD effects, 12 reconstructed intestinal anastomosis, 11 EBD failures due to gastrointestinal stenosis, 3 ERCP complications, 1 poor treatment effect of EUS-EGHS, 2 others. The reasons for choosing EUS-EGHS were 5 poor EBD effects, 5 EBD incapacitations due to gastrointestinal stenosis, 1 PTBD refractory, 2 PTBD intolerance cases. The success rate of the procedure was 95.7% vs. 100%, the response rate was 83.0% vs. 92.3%, and the complication rate within 2 weeks after the treatment was 10.6% vs. 15.3%. The median length of hospital stay after treatment was 21 days (3–129 days) vs. 11 days (3–22 days), the ratio of rehospitalization events was 30% vs. 30.7%, the median time from treatment to the event of rehospitalization was 92 days (12–305 Day) vs. 77 days (24–252 days). BSC cases was 43.5% vs. 92.3% (p < 0.05), median post survival time was 112 days vs. 89 days.

Conclusion: Most of the EUS-EGHS were administered to the patients with biliary and pancreatic cancer presented on BSC cases. Since it has the same degree of safety as PTBD, it seemed possible to continue performing EUS-EGHS more positively in terms of QOL. Also, it seemed possible to expand EUS-EGHS indication for the cases with any other organ cancer than pancreatic or biliary cancer and chemotherapists, but it is necessary to verify the safety of EUS-EGHS in the future.

Disclosure: Nothing to disclose

P0249 ROLE OF INTERVENTIONAL RADIOLOGY IN PEDIATRIC GASTROINTESTINAL DISEASES - A LARGE TERTIARY CENTER EXPERIENCE
Z Nabi,1 J Singh, R Chavan, U Shava, D.N Reddy
1Asian Institute of Gastroenterology, Gastroenterology, Hyderabad, India

Contact E-Mail Address: zaherrnabi1978@gmail.com

Introduction: Interventional radiology (IR) is an indispensable component of multidisciplinary care in various gastrointestinal (GI) diseases. The available evidence has shown safety and utility in children with GI disorders. The aim of the present study is to analyze the role of interventional radiology in pediatric GI diseases.

Aims and Methods: In this study, we aim to analyze the outcomes of IR in various pediatric GI diseases.

Results: The data of children < 18 years who underwent radiological intervention for various GI disorders during study period (2009–2017) were analyzed, retrospectively. The indications for interventions included vascular (Budd Chiari syndrome, pseudoneurysm) and nonvascular (pancreatic fluid collections, cholangitis and anastomotic biliary strictures). All the interventions were performed with standard technique. The indications for intervention in children with pancreatic fluid collections included unsuitability of endoscopic drainage or collection at multiple sites. Percutaneous transhepatic biliary drainage was carried out in children in whom endoscopic retrograde cholangiopancreatography was unsuccessful or not feasible. The outcomes of radiological intervention including success and adverse events were assessed.

Results: A total of 93 children (mean age 13.45 ± 4.09) underwent radiological interventions for vascular (chronic Budd Chiari syndrome 14, pseudoneurysm 28) or non-vascular (pancreatic fluid collections 33, hepatitis/choleojenynostomy stenoses or leaks 12, cholangitis 6) indications. Of 33 children who underwent percutaneous drainage of pancreatic fluid collections, clinical success was noticed in 32 children during a mean follow-up of 32.4 ± 21.66 months. 11 children developed persistent pancreatoctiocutaneous fistula of which 8 children were managed with endoscopic pancreatic ductal stenting and 3 underwent internalization of transgastric drain. In children who underwent stenting of hepatic vein or inferior vena cava for Budd Chiari syndrome, mean survival time was 18.57% during a mean follow-up of 24.1 ± 13.78 months. Adverse clinical outcomes were noticed in 4 children (28.57%) including persistence of ascites (1 child), requirement of re-intervention (1 child), and death (2 children: re-occlusion and intrahepatic.
biliary complications are a common cause of morbidity and mortality in liver transplantation (LT) recipients occurring in 10–25% of patients. Although with similar post-resection survival, the independent risk factors of LNM in the mERCC group, compared to those in the pERCC group, included large tumor size and LVI.

**Aims and Methods:** The aim of this study was to identify risk factors of LNM and compare clinicopathologic characteristic and prognosis of early pSRCC with early mSRCC. This retrospective study was conducted at our center between 2005 and 2015 in 796 radical gastric cancer gastrectomies. A total of 160 early signet ring cell carcinoma (ESRCC) radication resections were reviewed, in which 79 cases were early pSRCC and 81 cases were early mSRCC. Risk factors of LNM and clinicopathologic features of these 2 groups were statistically compared, including age, gender, tumor location, gross pattern, size, invasion depth, lymphovascular invasion (LVI), helicobacter pylori (Hp) infection, atrophic gastritis, and LNM. Patients were follow-up for post-resection survival. The 5-year survival rate and disease-specific survival were estimated with the Kaplain-Meier method with a log-rank test and compared between the two groups.

**Results:** The overall 5-year survival rate for ESRCC was 96.25%. Univariate analysis reviewed LVI and tumor size as the risk factors for lymph node metastasis (LNM). However, risk factors for lymph node metastasis (LNM) and clinicopathologic features of early mixed signet cell gastric carcinoma (mSRCC) was statistically compared, including age, gender, tumor location, gross pattern, size, invasion depth, lymphovascular invasion (LVI), helicobacter pylori (Hp) infection, atrophic gastritis, and LNM. Patients were follow-up for post-resection survival. The 5-year survival rate and disease-specific survival were estimated with the Kaplain-Meier method with a log-rank test and compared between the two groups.

**Conclusion:** Although with similar post-resection survival, the independent risk factors of LNM in the mERCC group, compared to those in the pERCC group, included large tumor size and LVI.

**Disclosure:** Nothing to disclose.
In univariate analysis, high distal contractile integral (DCI) median value on perative HRM was not performed, and 11/20 (55%) had prolonged pain after POEM. Of 22 patients who underwent POEM, 2 were excluded because preoperative HRM was not performed. The local ethics review committee granted approval.

Aims and Methods: The PTEG procedure was constructed from 2 existing general techniques. We also developed a rupture-free balloon (RFB) for the standard PTEG technique in 1997. 1 technique was puncturing of the esophagus with a RFB under ultrasonic control. The other was tube placement via the puncture site under fluoroscopic control. The standard PTEG procedure was thus a nonvascular interventional radiologic technique that did not require an endoscope. The Japan Association for PTEG (JA-PTEG) was established in 2002, and annual meetings of JA-PTEG were held every year. From 2005, under the guidance of the Ministry of Welfare, a clinical trial for PTEG was undertaken for 6 years in Japan, which confirmed its safety and efficacy. The Ministry of Welfare approved support for PTEG by Japanese national health insurance in 2012. Hands-on seminars with simulators for the PTEG procedure were held twice a year from 2014. In 2018, JA-PTEG initiated a system to technically certify physicians performing PTEG.

Results: PTEG has been performed in over 25,000 patients in Japan from 1994 to the present. We have also performed PTEG as an educational procedure in 341 patients. From 2018, JA-PTEG was performed on 186 individual members, 52 authorized institutions, 43 faculty members and 32 attending physicians. To date in 2018, JA-PTEG certified 8 physicians as those authorized to perform the standard PTEG procedure. For patients with intractable nausea and vomiting due to gastrointestinal obstruction caused by carcinoma, PTEG as a palliative treatment can quickly and effectively improve a patient’s quality of life. PTEG is also highly efficacious in enteral nutrition as an alternative to PEG. PTEG was originally born as a Japanese technique, and currently, it is still only performed within Japan.

Conclusion: We believe that the PTEG technique should be disseminated safely and effectively throughout the world.

Introduction: Percoral endoscopic myotomy (POEM) is a minimally invasive and curative treatment for esophageal dysmotility (1,2). However, significant pain persists in some patients after POEM.

Aims and Methods: This single-center study retrospectively investigated risk factors for pain after POEM. This study included consecutive patients who underwent POEM and high-resolution manometry (HRM) at the Okayama University Graduate School of Medicine between January 2016 and December 2017. A numerical rating scale (NRS) was used for pain assessment. A pain group (P-group: 3 days to achieve NRS <1) and a non-pain group (NP-group: <3 days) were compared. Data on comorbid disease, symptoms, and histological findings were obtained from medical records. All study participants provided informed consent. The local ethics review committee granted approval.

Results: Of 22 patients who underwent POEM, 2 were excluded because preoperative HRM was not performed, and 11/20 (55%) had prolonged pain after POEM. There was no significant difference in sex, age, and the amount of analgesic required during hospitalization between the P-group and NP-group. In univariate analysis, high distal contractile integral (DCI) median value on HRM and classification as a straight-type were risk factors for prolonged postoperative pain. In multivariate analysis, high DCI was a risk factor for prolonged postoperative pain.

Conclusion: The intensity of esophageal peristalsis before POEM may be a factor in prolonged postoperative pain.

ENDOSCOPIC PAPILLECTOMY IN TREATMENT OF PATIENTS WITH AMPULLARY NEOPLASMS: A SINGLE-CENTER EXPERIENCE

K Klyueva1, K Shishin2, I Nedoluzhko2, N Kurushkina1, L Shumkina1
1First Moscow State Medical University named after I.M. Sechenov. General Surgery, Operative Endoscopy. Department Moscow Clinical Scientific Centre, Moscow, Russian Federation
2Moscow Clinical Scientific Center, Dept. of Operative Endoscopy, Moscow, Russian Federation

Contact E-Mail Address: ivannedoluzhko@gmail.com

Introduction: Benign tumors of the ampulla of Vater occur in 0.4% to 0.12% of all tumors of the gastrointestinal tract (GI tract). However, malignant transformation of ampullary adenoma occurs in 60-65% of cases, so the common tactic of treatment is their removal. Regardless of the pathohistological structure of the tumor, endoscopic papillectomy is considered reasonably safe and most effective method compared to a more radical interventions such as pancreatoduodenal resection (PDR), surgery, or radiotherapy.

Aims and Methods: 37 endoscopic papillectomies were performed at the Moscow Clinical Research Center between April 2014 and January 2018. In most cases, the tumor was detected during a routine examination for other diseases. The preoperative examination protocol included duodenoscopy with biopsy, endosonography, CT or MRI, which excluded the presence of malignant lesions and the intraductal spread of the adenoma more than 1 cm. The sizes of the adenomas ranged from 1 cm to 5 cm. The aim of the study was to evaluate the effectiveness of endoscopic papillectomy in the treatment of patients with neoplasms of the ampulla of Vaier.

Results: 37 patients underwent endoscopic papillectomy, including 16 men and 21 women. Median age: 54 years (26–75). The average time of surgery was 85 minutes. In 26 cases, the removal of the adenoma was performed ‘en bloc’ (59.5%). In 11 cases, due to the presence of lateral spread of the tumor, fragmentation was performed (40.5%). Pancreatic stenting was successful in 31 patients (83.7%). Stenting was of the common bile duct in 9 patients (24.3%). In 2 cases, there was R0 resection. Morbidity included bleeding in 8 patients (21.6%), 2 cases of intraoperative perforation (5.4%), 1 of them was conservatively treated. The patient was operated in volume: laparotomy, suturing a perforation, drainage of the abdominal cavity. In 2 patients, the postoperative period was complicated by cicatrical stenosis of the bile duct opening (5.4%). The ERCP with the stenting of the common bile duct was performed. No death occurred.

Conclusion: Endoscopic papillectomy is characterized by lower morbidity and mortality and a shorter period of hospitalization. Compared with surgery, endoscopic ampullectomy appears to be a preferred treatment modality for small benign ampullary tumors with high success rate of tumor eradication.

Disclosure: Nothing to disclose

ENDOSCOPIC VACUUM THERAPY FOR TREATMENT OF UPPER GASTROINTESTINAL ANASTOMOTIC LEAKAGES: FIRST EXPERIENCE

A Pytakova1, K Shishin2, I Nedoluzhko2, L Shumkina1, N Kurushkina1
1Moscow Clinical Research Center c/o A.S. Loginov, Moscow, Russian Federation
2Moscow Clinical Research Center c/o A.S. Loginov, Dept. of Operative Endoscopy, Moscow, Russian Federation

Contact E-Mail Address: ivannedoluzhko@gmail.com

Introduction: Surgical interventions on the esophagus belong to the group of ‘high-risk’ operations, as they can lead to such formidable complications as insolvency, bleeding and the formation of postoperative fistulas and strictures. The results of systematic analysis of the largest series of clinical cases published in the last 20 years show the incidence of postoperative anastomotic leakage about 3% after open and 2.1% after laparoscopic surgery without significant differences between the two surgical approaches. However, analysis of the cumulative world experience shows the average incidence of anastomotic leakage at the level of 7-8%. These reports suggest that postoperative mortality rates in this patient group reach 30% and have no significant improvement toward reduction. The development of new surgical techniques and surgical interventions lead to an increase in mortality from 20 to 64%, which determines the use of minimally invasive technologies as a priority. Since 2006, a new method of endoscopic vacuum therapy in management of anastomotic leaks has become available in clinical practice.

Aims and Methods: From March 2015 to March 2018, anastomotic leakage of the esophagus was diagnosed in 12 patients (5 women, 7 men), including 9 patients with failure of esophagogastrectomy anastomosis, 3 patients with failure of
esophageal anastomosis. The average age was 67.5 years. Size of anastomotic perforation ranged from 0.5 to 3 cm. Strategy of treatment for all patients include adequate nutritional support by enteral feeding through the nasogastric tube, parenteral administration of combined nutrients, enterostomy, or a combination of several methods. Early anti-biotic therapy is necessary for the prevention and treatment of already developed mediastinitis and septic complications.

The complications were detected on the 1–7 days after surgery. Anastomotic leak was confirmed by radiological and endoscopic methods. Endoscopic vacuum therapy within the day of leakage detection (2–4 days after the surgery). Thus no additional sanation and draining interventions were required due to early diagnosis and adequate drainage of the anastomosis area. Polyurethane spongiform system, slightly smaller diameter or corresponding to the diameter of the esophagus, was mounted on a thermoplastic gastric probe and installed at the level of the perforation. Immediately after installation, the system was connected to a vacuum aspirator with a pressure of 100 - 125 mm Hg. Replacement of the system was carried out every 3–13 days. To fully close the irregularity, the new system was installed after 7 procedures. The decision to complete the therapy was carried out based on the results of endoscopic and X-ray examination in the absence of data for the presence of fistula.

Results: In total 57 procedures were performed: the number of replacements - 4 (1–7), the interval between procedures - 6 days (3–13 days), the duration of treatment -13 days (1–66 days). The success rate was 75%. There were 3 lethal outcomes, including 2 due to progressive cardiovascular failure with positive dynamics of local treatment. 1 patient died of multiple organ failure.

Conclusion: Endoscopic vacuum therapy is considered to be valuable and cost-effective method of treatment of anastomotic leaks and perforations of the upper GI tract.

P0258 THE SMART APPROACH TO SURGICAL TREATMENT FOR GASTRIC AND DUODENAL GISTS BASED ON PREOPERATIVE EUS-TYPING
S Dzhanthurbanova1, Y Starkov1, M Vyborny2
1Vishnevsky’s Institute of Surgery Dept. of Endoscopic Surgery, Moscow, Russian Federation
2A.V.Vishnevsky Institute of Surgery, Moscow, Russian Federation

Contact E-Mail Address: seda-d@mail.ru

Introduction: Surgical treatment is the treatment of choice for the resectable GISTs. The objective of surgical treatment is to remove the tumor completely, thus improving the survival. The decision to perform the surgery is based on the results of preoperative evaluation. Endo-US, based on the localization and size of the tumor, is considered an important tool for the decision-making process in GISTs.

Aims and Methods: Aims were to develop and demonstrate different surgical techniques of laparoscopic or endoscopic resection for GISTS based on classification of EUS-typing for optimal choice of treatment. By the ‘smart’ approach we imply the approach which allows us to make a surgery less invasive and more accurate, including more functional results with no increase of complications. The EUS-classification of GISTS was created based on the analysis of the treatment of 80 patients with gastric and duodenal GISTS. The principles of classification included the following criteria:

- Location of tumor base in relation to GI lumen
- Size of the tumor base ("growing point")
- Type of growth in relation to GI lumen
- The EUS-typing includes Type I, Type II, Type III (a,b,c,d) tumors

Objectives and approaches:

- Endoscopic removal of tumor by means of: Endoscopic submucosal dissection (large size) Endoscopic mucosal resection (small size)

Type I
Endoscopic enucleation of tumor after resection of covering mucosa
Endoscopic tunneling dissection
Type Ila
Endoscopic tunneling dissection
Type IbII
Laparoscopic atypical resection after gastrotomy (duodenotomy)
Endoscopic tunneling dissection (advanced endoscopic surgeon and small tumor size)
Laparo-endoscopic hybrid procedures

Type IIC
Laparoscopic atypical (wedge) resection
Laparoscopic enucleation of tumor
Laparoscopic atypical stapler resection

Results: Patients with gastric and duodenal GISTS underwent laparoscopic resection. The EUS classification of GISTS was based on the analysis of 80 patients: 49 patients underwent Type I, 15 patients underwent Type II, 12 patients underwent Type IIIa, 4 patients underwent Type IIIb. The mean follow-up period was 42 months (range 3-74 months) with no local or distant recurrence or stenosis at the site of surgery.

Conclusion: The classification of GISTS based on EUS-typing allows to select the optimal approach individually for each patient to perform surgery more accurate and less invasive.

P0260 A COMPREHENSIVE COMPARISON OF THE FIVE LEADING SCORING SYSTEMS FOR PERITONEAL CARCINOMATOSIS FROM COLORECTAL ORIGIN TO SELECT CRS/HIPEC CANDIDATES
M Engbersen1, L van ‘t Santi-jansen1, H van Eden1, D.M Lambregts1, J Velzing1, R Rees-Tan1, A Aalbers2, N Kook3, M Lahaye4
1The Netherlands Cancer Institute, Radiology, Amsterdam, Netherlands
2The Netherlands Cancer Institute, Surgery, Amsterdam, Netherlands
3The Netherlands Cancer Institute, Department of Radiology, Amsterdam, Netherlands

Contact E-Mail Address: mj.lahaye@gmail.com

Introduction: Multiple surgical scoring systems have been developed to assess the extent of peritoneal carcinomatosis in colorectal patients. These scoring systems are used as important predictors of surgical outcome in cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (CRS/HIPEC). Diffusion weighted magnetic resonance imaging (DW-MRI) could allow for the assessment of these surgical scores preoperatively and non-invasively.

Aims and Methods: The purpose of the study is to compare the performance of these scoring systems determined on MR images, for predicting whether a complete resection was feasible in CRS/HIPEC candidates with colorectal cancer. Between February 2016 and October 2017, colorectal cancer patients considered for CRS/HIPEC who underwent DW-MRI were included. The DW-MRI images were retrospectively and independently assessed by 2 abdominal radiologists. Both radiologists were blinded for the clinical parameters. Clinical parameters were obtained from the patient files. 5 most-used models were selected, namely the Peritoneal Surface Disease Severity Score (PSDSS), Region Count, Simplified Peritoneal Cancer Index (SPCI), Peritoneal Cancer Index (PCI), and the Colorctal Peritoneal Metastases Prognostic Surgical Score (COMPASS). The performance of the scoring systems was assessed by receiver operator characteristics (ROC) analysis for predicting complete resection and the area under the curve (AUC) was calculated for every model.

Results: In 82 patients, the scores could be accurately constructed for all 5 methods. The mean age was 62.80 (± 10.53) and 46/82 of the patients were female. Of these patients 70% (58/82) had undergone a successful surgical procedure with a curative intent, of which 84% (49/58) underwent a CRS/HIPEC procedure. In 20 patients, an inoperable amount of peritoneal carcinomatosis was determined at surgery. ROC curve analysis for predicting a complete resection showed AUCs of 0.79, 0.79, 0.82, 0.83, and 0.89 for PSDSS, Region Count, SPCI, PCI, and COMPASS, respectively. Both radiologists were blinded for the clinical parameters. Clinical parameters were obtained from the patient files. 5 most-used models were selected, namely the Peritoneal Surface Disease Severity Score (PSDSS), Region Count, Simplified Peritoneal Cancer Index (SPCI), Peritoneal Cancer Index (PCI), and the Colorctal Peritoneal Metastases Prognostic Surgical Score (COMPASS). The performance of the scoring systems was assessed by receiver operator characteristics (ROC) analysis for predicting complete resection and the area under the curve (AUC) was calculated for every model.

Conclusion: This study shows that DW-MRI might be used for less invasive and preoperative patient selection of colorectal patients considered for CRS/HIPEC. The COMPASS model was the best model to select CRS/HIPEC candidates with MRI.

Contact E-Mail Address: r.s.filip@wp.pl

Introduction: Preoperative evaluation of MR images may not be sufficient for planning the anastomotic surgery and the internal supports. 3D printing allows to obtain spatial structures in 1:1 scale with unprecedented precision.

Aims and Methods: Optima MR360 Advance 1.5T (GE Healthcare) with a 16-channel TOTAL BODY coil was used. The imaging protocol consisted of high-resolution axial and coronal T2-weighted images with a matrix size 512 × 512, a slice thickness of 2 mm and zero spacing scans. DICOM images were imported into 3D Slicer v4.8.0. Firstly anal fistula was modelled on the basis of axial images. Fistula locations, anus and anal canal were marked with a different color. The last step of the model was to mark the skin that was connected to the anus and contact areas of the fistula with the skin. The prepared model was then exported to an STL format file. Blender 2.77a was used to smooth the edges of the model, then 3D program allowing the color to be assigned to individual model element was used. The final version of the model contained 958 layers. The anal fistula model was printed using the 3D Prodjet 460 Plus printer (3D Systems). The development of the model, including printing took approx. 9 hours.

Results: Acessibility of rotatable 3D before surgery allows more precise detection of the location and the degree of the perianal disease. Moreover, this may also lower the inter-observer bias connected with the different skills to interpret complex MR imaging before planned surgery.
Conclusion: The proposed use of 3D printing technology in the case of anal fistula will allow for effective surgery planning.

Contact E-Mail Address: s.perin@ucl.ac.uk

Introduction: Severe gastrointestinal disorders including chronic intestinal pseudo-obstruction affect the neuromuscular compartment of the small intestine. Very little is known, however, about the repair and regeneration of damaged or dysfunctional smooth muscle.

Aims and Methods: Our study aims to investigate the potential of human foetal gut mesoangioblast-like cells for enteric smooth muscle regeneration as a possible treatment for enteric myopathies and related disorders.

Mesoangioblasts-like cells (MABS), isolated from human foetal midgut (under ethical approval from the UK Human Developmental Biology Resource at UCL Great Ormond Street Institute of Child Health), were expanded and TGFß used for 7 or 14 days to induce smooth muscle differentiation in vitro. Immunohistochemistry, FACS analysis and calcium imaging were performed to characterise MABS and smooth muscle-derived cells. After 14 days in culture in vitro, MABS were transplanted in vivo into ileal tissue in nude-SCID mice (under UK licence, PPL 70/622) and cell engraftment assessed with immunohistochemistry after 4 weeks.

Results: Immunohistochemistry and FACS analysis showed that foetal gut MABS have high proliferative capacity (~55% of cells are Ki67+ in culture), are positive for mesenchymal markers CD90 and CD146 (~98% for both markers) and for pericyte markers NG2 and PDGF-Rß (~90% and ~20–30% respectively). After 7 days in culture with TGFß-treatment, MABS expressed smooth muscle proteins SM22 and calponin, and showed intracellular calcium transients in response to carbachol. After 14 days MABS also expressed smoothelin, a marker of mature smooth muscle. In vivo, transplanted MABS were able to engraft, distribute in the muscle layers of the ileum and differentiate into SM22 positive smooth muscle cells.

Conclusion: Here we demonstrate that MABS can be successfully isolated from human foetal gut. In vitro and with TGFß-treatment MABS showed an increasing ability to differentiate into smooth muscle cells and respond to carbachol stimulation, thus supporting their functional potential. The ability of MABS to differentiate into mature smooth muscle cells in vitro and engraft in vivo provides proof of principle for their potential use as a treatment for enteric smooth muscle disorders.

Introduction: Negative circumferential resection margins (CRM) are the cornerstone for curative treatment of patients with locally advanced rectal cancer (LARC). Unfortunately, perioperative techniques for evaluation of resection margins are lacking, whereas standard histopathological examination is time-consuming. In this study, we evaluated the feasibility of optical molecular imaging as a tool for discrimination of resection margins at the surgical theater, i.e. Image-Guided Pathology (IGP), to improve clinical decision making.

Aims and Methods: Fluorescence imaging data of fresh surgical specimens and subsequent bread-loaf slices from patients with LARC (NCT01972373) were analyzed as a side study. All patients were administered intravenously with 4.5 mg of the fluorescent tracer bevacizumab-800CW 2–3 days prior to surgery. 7 patients met the inclusion criteria for correlation of fluorescence intensities in fresh surgical specimens with histology, to evaluate resection margins. For analysis of bevacizumab-800CW localization in bread-loaf slices, sufficient data was available from 17 patients. A receiver operating characteristics (ROC) curve was plotted to determine the mean fluorescence intensity (MFI) cut-off value for tumor detection.

Results: Using IGP, in one patient a histologically confirmed tumor-positive CRM was predicted correctly at the surgical theater. Tumor-negative CRMs were predicted correctly in 4 patients using IGP. 1 tumor-positive CRM could not be detected; however, this positive margin was based on the presence of only one microscopic tumor deposit in the CRM. 1 close CRM (1.4 mm) was identified as tumor-positive. Optical imaging enabled a clear differentiation between tumor and surrounding tissue in the bread-loaf slices (n = 42) of all 17 patients in vivo. In our limited sample size, an optimal MFI cut-off value of 5085 was determined based on the ROC curve, with a sensitivity and specificity of 97.3% and 99.7% respectively.

Conclusion: We demonstrate for the first time the potential of IGP for identification of positive resection margins directly after surgery in patients with LARC. Clearly, this might change current peri-operative decision making with regard to additional targeted resections or intraoperative brachytherapy. Based on the initial results from this study, a standardized methodology was developed to confirm these findings in a subsequent larger IGP study.

Introduction: The time interval between CRT and surgery in rectal cancer patients is still subject of debate and concerns exist regarding increased postoperative complication and local recurrence rates after longer waiting.

Aims and Methods: To evaluate the impact on short- and long-term outcomes of variation in practice related to MRI restaging and time interval between neoadjuvant chemoradiotherapy (CRT) and surgery in rectal cancer patients. Patients were selected from a collaborative rectal cancer research project including 71 Dutch centers. Patients were subdivided into 2 groups according to the time interval from the start of preoperative CRT to surgery (<14 and >14 weeks).

Results: From 2095 registered patients, 475 patients received preoperative CRT. MRI restaging was performed in 79.4%, with a median CRT-MRI interval of 10 (IQR 8–11) weeks, and median MRI-surgery interval of 4 (IQR 2–5) weeks. Short and long interval groups consisted of 224 and 251 patients, respectively. Pathological complete response rate (n = 34 (15.2%) vs. n = 47 (18.7%), p = 0.305) and CRM involvement (9.7% vs. 15.9%, p = 0.145) did not significantly differ. 30-day surgical complications were similar (20.1% vs. 23.1%, p = 0.943). No significant differences were found for local- and distant-recurrence rates and disease-free and overall survival.

Conclusion: These real-life data reflecting routine daily practice in the Netherlands showed substantial variability in use and timing of restaging MRI after preoperative CRT for rectal cancer, as well as time interval to surgery, but with similar short- and long-term outcomes.

Introduction: Laparoscopic ventral mesh rectopexy (LVR) is gaining wider acceptance as the preferred procedure to correct internal as well as external rectal prolapse associated with obstructed defecation syndrome (ODS) and/or faecal incontinence.

Aims and Methods: The aim of our study was to analyse functional outcome and quality of life (HRQL) after laparoscopic ventral rectopexy for symptomatic internal prolapse and/or rectocele with ODS. Prospectively collected data on patients who underwent surgical repair for rectal prolapse were analysed in 46 consecutive female patients operated between January 2011 to April 2018. Mean age was 62 years (range 25-
Results: Mean operative time was 151 min (range 75 - 240). Conversion rate to open technique was 10.8 %. There was no post-operative mortality or major complication. Mean hospital stay was 4 days (range 2 - 7). Among a mean follow-up of 26 months (range 3 - 71 months), we observed no recurrence of prolapse or rectocele. Comparing Wexner score before and after LVR we observed an improvement in painful evacuation (p = 0.001), minims in lavyatory attempts (p = 0.008), feeling incomplete evacuation (p = 0.017) and abdominal pain (p = 0.017). Moreover, the global Wexner score was significantly improved from 13.60 to 10.18 (p = 0.000). Similarly, SF-36 items improved after the surgery, especially in term of Physical Functioning (p = 0.005). The comparison of preoperative SF-36 score with matched healthy controls demonstrated a significant difference in particular in Physical Functioning (p = 0.001) and Bodily Pain (p = 0.023). On the contrary, the comparison of post-operative SF-36 scores and healthy controls scores showed a significant difference only in terms of Bodily Pain (p = 0.055). No worsening of continence status, constipation or sexual function was observed. No significant improvement was observed in urinary incontinence. None patient experienced persistence or recurrence of the prolapse.

Conclusion: LVR appears to provide a sustained improvement in HRQL, constipation and incontinence in patients with ODS without worsening constipation with low morbidity and recurrency.

Disclosure: Nothing to disclose.

P0266 ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) VERSUS TRANANAL ENDOSCOPIC MICROSURGERY (TEM) FOR THE TREATMENT OF EARLY RECTAL CANCER: COMPARISON OF LONG-TERM OUTCOMES C Kimura1, F S Kagawati2, C F Saparapan Marques2, C S R Nahas4, V Segate1, B da Costa Martinis3, L H Lenz Tolentino2, U Ribeiro3, F Maluf-Filho4, S C Nahas3

Introduction: Methods for the local treatment of early rectal cancer have been developed in the recent years. In this scenario, the transanal endoscopic microsurgery (TEM) and the endoscopic submucosal dissection (ESD) have played an important role. Both have their own advantages and drawbacks, but there are still few studies comparing them. Previous studies have shown that both techniques have similar short term outcomes (1). Studies assessing long-term outcomes, however, are scarce.

Aims and Methods: To compare long-term outcomes between ESD and TEM for the treatment of early rectal cancer.

Findings: From January 2017, 103 procedures were performed (either ESD or TEM). Lesions submitted to ESD were previously assessed by magnification endorectal ultrasound before the procedure.

Data regarding age, surgical risk, early and late complication rates, recurrence and anatomopathological report were collected retrospectively. Qualitative variables were submitted to a chi-square analysis and the quantitative ones, to a t-test.

Results: The mean follow-up of these patients was 34 months. 74 of them (71.8%) were submitted to ESD and 29 to TEM (28.2%). The average age in the ESD group was 65.5 years and 51.3% of those patients were female. Among the patients undergoing TEM, 7 (24.13%) had rectal pain, diarrhea or incontinence and anal stricture presented mucorrhea, fecal urgency and/or incontinence and anal stricture.

In the ESD group, 7 patients (9.46%) had early complications, 2 of which were Clavien I, 3 Clavien II and 2 Clavien III. In the TEM group, 5 patients had complications (17.2%), of which 2 were Clavien I, 1 Clavien II, 1 Clavien III and 1 Clavien IV (p = 0.19). The average days of hospitalization was 3.4 among the ESD patients and 6.9 among the TEM (p = 0.015).

During the first post-operative month, 10 patients (13.5%) from the ESD group presented faecal urgency and/or incontinence and anal stricture requiring dilatation. By the end of 18 months, all patients were asymptomatic. Among the patients undergoing TEM, 7 (24.13%) had rectal pain, diarrhoea or fecal incontinence. After 18 months, 6 were asymptomatic and 1 persisted with rectal pain.

The lesions removed either by ESD or TEM had similar rates of en-bloc resection - 89.2% and 96.5%, respectively (p = 0.23) and R0 resection - 85.13% and 82.6%, respectively (p = 0.742). The anatomopathological analysis of the lesions submitted by ESD showed 26.3% of adenomas, 64.86% of intramucosal adenocarcinoma, 4.3% sm1 adenocarcinoma and 4.05% of sm2-3 adenocarcinoma (non-curative resection). In the TEM group, 31% were adenomas, 44.8% of intramucosal adenocarcinoma, 7% of sm1 adenocarcinoma and 17.2% of sm2-3 adenocarcinoma. Therefore, the ESD had a higher percentage of curative resections (p = 0.002).

Among the patients undergoing TEM, there was a 24.13% recurrence rate, against 1.3% in the ESD group (p = 0.0001).

Conclusion: The ESD, compared with the TEM, showed better results, enabling the treatment of significantly larger lesions, with a higher curative rate, less hospitalization days and lower recurrence rates.

Disclosure: Nothing to disclose.

Introduction: Abdominal pain is one of the most common symptoms of inflammatory bowel diseases (IBD). However, its molecular basis has not been fully characterized yet. It has been shown that chronic elevation of luminal serotonin increases visceral pain and that elevated secretion of this neurotransmitter in the gut leads to the exacerbation of inflammation. On the other hand, it is well established that inhibited endocannabinoid signaling in the gut lowers pain threshold and endogenous cannabinoid receptor agonists reverse this effect and exhibit antiinflammatory and anti-inflammatory properties.

Aims and Methods: The aim of this study was to test the hypothesis that chronic administration of serotonin causes disruption of the cannabinoid signaling leading to visceral pain in the course of colitis.

Methods: We used 3% DSS in drinking water to induce colitis in mice. Serotonin was systemically administered for 5 days starting from day 3 post-DSS and each day visceromotor response to colorectal distention (CRD) was measured. Selective 5-HT3 and 5-HT4 receptor antagonists were used to examine the mechanism of action of serotonin. Macroscopic evaluation of the colonic damage was performed. Expression of cytkines, serotonin and cannabinoi (CB) receptors as well as enzymes responsible of biosynthesis and degradation of endocannabinoids were investigated. Moreover, serotonin as well as endocannabinoids were measured to assess the change in levels.

Results: DSS caused severe intestinal inflammation represented by increased macroscopic fissure score as well as upregulation of TNFα, IL-1β and IL-6. Chronic, systemic treatment with serotonin led to significant increase in the concentration of this hormone in the colon and simultaneous decrease of the endocannabinoids, CB1 and CB2-receptors. The visceromotor response to CRD was significantly higher in the serotonin-treated animals compared to the vehicle group and this effect was dependent on 5-HT3 but not 5-HT4 receptors. Moreover, chronic serotonin administration led to the downregulation of CB1, but not CB2, and decreased N-acetyl phosphatidylethanolamine-specific phospholipase D (NAPEPLD), which is responsible for synthesis of anandamide and other N-acylethanolamines, and these effects were reversed by the 5-HT3 receptor antagonist granisetron.

Conclusion: Here we present a novel mechanism that may be responsible for the increased visceral pain in intestinal inflammation. Our study suggests that pharmacological blockade of serotonin signaling in the gut might be of benefit in severe cases of abdominal pain in IBD patients.

Disclosure: Nothing to disclose.

P0268 UROTENSIN II RECEPTOR EXPRESSION IN ULCERATIVE COLITIS: RELATIONSHIP WITH ENDOCANABINOIDS AND PHARMACOLOGICAL ACTIVITY OF UTR PE A.G Gravina1, M Dallio2, C Taccelli2, M Martorano2, C Loguercio1, A Federico1

Contact E-Mail Address: marcello.dallio@gmail.com

Introduction: Urotensin II (U-UTR) is a vasoactive peptide that interacts with a specific receptor, UTR (1). Recently our group has demonstrated increased UTR expression both in adenocarcinoma cell lines and adenomatous polyps and even greater in colon carcinoma samples when compared to healthy colon samples of the same patients. We also showed that an UTR agonist induced an
increase in colon adenocarcinoma cells growth in vitro, while the UTR block with a specific antagonist caused an inhibition of their growth and an inhibition of about 50% both of motility and cell invasion (2).

Aims and Methods: There are no data in the available literature (UC), and we therefore evaluated the expression of UTR in UC patient biopsy and in healthy tissue. We therefore also have colic tissue samples taken in these subjects. Evaluation of receptor expression was performed by RT-PCR. The ANOVA test (p < 0.05); b) correlation of UTR expression with endoscopic and histological activity of disease in most study patients. We found a greater expression of UTR in patients with a Mayo Endoscopic Score 2 and with severe histologic only in 4 patients.

Introduction: Inflammation is predominating of inflammatory intestinal lesions. Hypoxia inhibits hypoxia-inducible factor prolyl hydroxylase (HIF-PH), which stabilizes HIF and induces HIF downstream gene expression in the colon. HIF-1, a complex consisting of inducible HIF-1 alpha and constitutive HIF-1 beta, induces the expression of protective barrier genes in colon epithelial cells and plays a critical role in protecting against inflammatory bowel disease (IBD). HIF-PH inhibitors are thought to have the potential to enhance mucosal barrier function through HIF-1 alpha stabilization. We found out that DS-1093a, a HIF-PH inhibitor, might have the potential to be a novel IBD drug with mucosal healing activity.

Aims and Methods: To elucidate the effect of DS-1093a on IBD, we administered DS-1093a to colitis mice. Experimental colitis was induced in male BL-6 mice by dissolving Dextran Sodium Sulphate (DSS) in their drinking water for 8 days. DS-1093a was administered to DSS mice in the feed for 8 days or by intra-rectal administration (IRA) once a day until day 7. The disease conditions (colon length, body weight, and diarrheal score), histopathology (HE staining, AB-PAS staining, and HIF-1 alpha immunohistochemistry) of colon, and haematological parameters were analysed on day 8. Colon and serum of each mouse were also collected on day 8. The mRNA expression was analysed by qRT-PCR. IRA was conducted by administering the solution between the cecum and the rectum via a catheter through the anus.

Results: DS-1093a improved total body conditions, as shown by body weight, colon length, and diarrheal score in DSS colitis mice. In the histopathological analysis, colitis mice showed intestinal tissue injury; however, treatment of DS-1093a reduced the mucosal injury and increased normal tissue region. AB-PAS (mucin) stained section of the colon showed DS-1093a normalized mucosa proliferation in colitis mice. DS-1093a prevented the activation of immune cells by colitis, and DS-1093a suppressed inflammatory cytokine gene expression in the colon epithelial cells. DS-1093a induced HIF-1 alpha accumulation in the nucleus of mucosal epithelial cells. In contrast, DS-1093a induced excess erythropoiesis by 8-day feeding administration. IRA of DS-1093a is suggested to maintain the functional integrity of colon epithelial cells. Owing to mucosal barrier improvement, DS-1093a prevented immune cell activation by colitis, suppressed inflammatory cytokine gene expression in colon epithelial cells. Mucosal damage was correlated with the expression of HIF-1 alpha. These results suggested that DS-1093a had a strong efficacy for IBD in colitis mice with novel mechanisms for normalizing colitis mucosa. Moreover, topical exposure of DS-1093a to the colon can widen the efficacy margin between IBD and erythropoiesis.

4University of Gothenburg Saehgrenska Academy Dept. of Microbiology and Immunology, Sahlgrenska Academy, Gothenburg, Sweden

Contact E-Mail Address: anna.strombeck@microbio.gu.se

Introduction: Dysbiosis has been proposed to be a key antigenic driver for the inflammation in Crohn’s disease (CD). However, the role of the fecal microbial composition for the post-operative disease course in CD patients remains to be established.

Aims and Methods: Our aim was to determine if the fecal microbial composition at the time of ileocaecal resection or 1 year after surgery was associated with endoscopic disease recurrence in CD patients 1 year after surgery. Patients with CD who had undergone ileocaecal resection were included in the study. Approximately 1 year after surgery, clinical evaluation by ileocolonoscopy was performed. The mucosa in the neoterminal ileum and ileocolonic anastomosis was assessed according to Rutgeerts’ scoring system. 5 or less aphthoid lesions were considered as remission (i,0-1), and > 5 aphthoid lesions, lesions or ulcers confined to the anastomosis or diffuse inflammation were considered as endoscopic disease recurrence (i,2-4).

Fecal microbial composition was analyzed using the Genetic Analysis GA-map Dysbiosis test, which consists of 54 DNA probes targeting >300 bacteria on different taxonomic levels.

Logarithmic data were analyzed in SIMCA using orthogonal partial least squares discriminant analysis (OPLS-DA) to identify discrimination between groups. Bacteria with the strongest discriminatory power were further analyzed by univariate analysis (Mann-Whitney U-test).

Results: In total, 22 CD patients from Southwestern Sweden (8 women) with median age 30 (17-63) years and median disease duration of 3 (0-11) years at the time of resection was included. At inclusion, 8 patients were treated with 5-aminosalicylic acid (5-ASA), 14 with corticosteroids, 11 with thiopurines, 1 with anti-tumor necrosis factor, and 4 patients had none of the treatments above. At the one year follow up, 9 patients were treated with 5-ASA, 2 with corticosteroids, 6 with thiopurines, and 8 patients had no treatment. Stool samples were collected by 9 patients at the time of resection and by 21 patients at the 1 year post surgery follow-up. At the 1 year follow up, 13 patients were in endoscopic remission (i,0-1) and 9 patients had endoscopic recurrence (i,2-4).

At the time of resection, fecal microbial composition discriminated patients whom the 1 year post surgery follow-up were in endoscopic remission or with recurrence, respectively, although the predictive ability was low (R2 = 0.94, Q2 = 0.01, i,0-1: n = 5; i,2-3: n = 4). Similarly, fecal microbiota at the 1 year post surgery follow-up discriminated patients in endoscopic remission from those in recurrence, yet with low predictability (R2 = 0.71, Q2 = 0.47; i,0-1: n = 3; i,2-3: n = 8).

The OPLS-DA models at the time of resection and at 1 year post surgery follow-up demonstrated that endoscopic remission was associated with a higher bacterial abundance, both among the Firmicutes and Bacteroidetes, as compared to recurrence. In addition, univariate analysis showed that patients in remission one year after surgery tended to have higher abundance of Pseudomonas spp at the time of surgery (p = 0.06) and Parabacteroides spp at time of 1 year post surgery follow up (p = 0.08), as compared to patients with recurrence.

Conclusion: Our results suggest that CD patients with endoscopic disease recurrence 1 year after ileocaecal resection have lower fecal bacterial abundance, both at the time of resection and 1 year after surgery, as compared to patients in remission. Thus, a lower intestinal bacterial abundance may be a contributing factor to disease relapse in these patients.

**P0273** THE SYSTEMIC INFLAMMATORY PROTEIN Profiles differentiate BETWEEN PATIENTS WITH INFLAMMATORY AND FUNCTIONAL GASTROINTESTINAL DISEASES

I Moraes1, M.K. Magnusson1, B Jonefält1, A Polster1, J Sundin1, H Törnblom1, H Strid1, M Simrén1, L Ohman1

1University of Gothenburg, Dept. of Microbiology and Immunology, Gothenburg, Sweden
2University of Gothenburg, Department of Internal Medicine and Clinical Nutrition, Göteborg, Sweden
3University of Gothenburg, Dept. of Gastroenterology and Hepatology, Gothenburg, Sweden

**Introduction:** Patients with ulcerative colitis (UC) may suffer from irritable bowel syndrome (IBS)-like symptoms during periods of remission. Due to the low-grade immune activation repeatedly reported in IBS, it has been suggested that the underlying inflammatory mechanisms of the 2 diseases overlap or are part of the same spectrum.

**Aims and Methods:** We aimed to determine if the systemic protein profiles (SysPP) differ between UC and IBS patients, and if SysPP are linked to presence of inflammation and/or functional symptoms. Patients with active ulcerative colitis (UCA), UC patients in remission with IBS-like symptoms (UCR-IIBS), UC patients without IBS-like symptoms (UC-IIBS) were included in the study. SysPP of all groups revealed 2 clusters; 1 cluster composed of IBS patients and HS, and 1 cluster of UC patients. Logarithmic data were analyzed in SIMCA using principal component analysis (PCA) and orthogonal projection least square discriminate analysis (OPLS-DA) with a Variable Importance for the Projected (VIP) cut-off of ≥0.7 to identify proteins discriminating between groups. Univariate analyses were performed using Mann-Whitney U test and false discovery rate analysis.

**Results:** In total, 166 subjects (UCa, n = 40; UCR-IIBS, n = 45; UCR-IIBS, n = 20; IBS, n = 21) were included in the study. PCA of SysPP of all groups revealed 2 clusters; 1 cluster composed of IBS patients and HS, and 1 cluster composed of all UC patients, irrespective of disease activity or presence of IBS-like symptoms. Variables most important for the clustering were higher levels of co-stimulatory molecules such as CD40 and tumor necrosis factor super family member 14 (TNFSF14), cytokines such as interleukin (IL)-8 and IL-6, oestrogen-M (OSM), chemokines such as chemokine ligand 3 (CCL3), other inflammatory markers such as extracellular newly identified receptor for Dectin-1 (EN-RAGE), sulfotransferase 1A1 (ST1A1), axin 1 (AXIN1), and an apoptotic marker, caspase-8 (CASP8), among UCA/UC-IBS/UC-IIBS as compared to IBS/HC.

When comparing IBS and UCR-IIBS patients based on the SysPP, OPLS-DA discriminated the 2 groups with high predictability (R² = 0.92, Q² = 0.82).

Introduction: Crohn’s disease (CD) is a chronic inflammatory condition with multiple phenotypes of which the fibrostenotic type carries significant morbidity.

Aims and Methods: We aimed to look at histological changes in resected terminal ileal (TI) specimens using this novel scoring system (1). Results: Among 48 patients (M = 25; median age 45 years, range 21–72 years), 41 were Caucasian, 4 Asian and 3 Afro-Caribbean in ethnicity. The median duration of disease was 7 years (range 3 months – 39 years); majority had ileo-colonic distribution with stricturing disease; 16 patients were on thiopurines, 19 on steroids.

Conclusion: Our results suggest that pure fibrostenotic disease is uncommon and chronic inflammation is a prominent feature of this phenotype. In addition to fibrosis, muscle hyperplasia is an important component. Other components such as volume expansion, neuronal hypertrophy and adipose hyperplasia are likely to be important in different layers of the bowel. This suggests that inflammation driven tissue remodelling leading to stricture formation is a complex process resulting in a multitude of changes and not simply characterised by excess deposition of fibrotic tissue.

Introduction: Inflammatory bowel diseases (IBD) often involve the ileoceleal region of the intestine. In addition, accumulating epidemiological studies have suggested that appendectomy may reduce the risk of ulcerative colitis. These findings imply that clinical immune response may be considered to affect the development of IBD, but the mechanism is still unclear.

Aims and Methods: The aim of this study is to analyze the ileocecal immune response in the setting of IBD. To this end, oxazolone colitis model was induced in mice under various backgrounds, conditions (including appendectomy), and methods (such as 5-dimensional intravital imaging).

Results: Wild type C57BL6 (WT) mice sensitized with oxazolone revealed lymphocyte infiltration and ulcerations in the colon accompanied by expanding cecal lymphoid follicles (CLF), which was the focus of our study. Mice underwent appendectomy before oxazolone treatment resulted in attenuated colitis with regards to both clinical disease activity and histopathology index with associated decrease of pro-inflammatory cytokine production. Similar clinical and histo-pathological changes were also observed in mice lacking mature B cells, µMT.

Conclusion: Real-time analysis of B cell activity in the CLF was accomplished by using mice with B cell-specific Ca2+ biosensor, YC3.60, expression. Utilizing intraval imaging, B cell activation with frequent Ca2+ influx was observed in the CLF during the early phase of colitis development. B cells in the CLF expressed higher level of activation markers, such as major histocompatibility complexes, compared to that of the non-colitis control, even though there were no significant changes in the ratios of immunoglobulin (Ig) classes on the B cell surface of the CLF.

P0276 THE CHANGE OF THE ANG, ACE2 AND ANG,1-7, ON TNBS-INDUCED EXPERIMENTAL COLITIS IN MICE AND THE RESEARCH ABOUT PROTECTIVE EFFECT OF MICA

B Zhang, M Shen, L Ye, B Lv, L-N Meng
The First Affiliated Hospital of Zhejiang Chinese Medical University, Gastroenterology, Hangzhou, China

Contact E-Mail Address: s167725@163.com

Introduction: Ulcerative colitis (UC), a chronic intestinal inflammatory condition that affects millions of people worldwide, is characterized by leukocyte infiltration and upregulation of proinflammatory cytokines. Mica is a silicate mineral drug. Previous studies have shown that mica can promote gastrointestinal mucus proliferation and epithelial cell regeneration in vivo, and inhibit cell apoptosis and activation of neuronal proliferation.

Aims and Methods: We aimed to explore the roles of Ang, ACE2 and Ang,1-7, in experimental colitis and investigate the prevention and possible mechanism of mica.

36 male BALB/C mice of clean grade were randomly divided into control group, model group and mica group, 10 mice in each group. Experimental colitis mice were made by TNBS. In first day, the model group and mica group were initiated by intrarectal administration of saline water (10ml/kg). From the second day, the control group and model group were
intrarrectally administrated with (10ml/kg/d), the mica group was intrarrectally administrated (180mg/kg/d) until the fourth day, then the mice were killed. Macroscopic score and histological score were assessed. Protein expressions of Ang, ACE2 and Ang1-7, were measured by immunohistochemist. ELISA was used to determine colonic tissue inflammatory factor IL-17A and IL-10 level.

Results: 1) Macoroscopic total damage: Colonic macroscopic damage index of mice in normal, the model group was much higher than that of the control group (4.00±0.89 vs. 0.00±0.00, p<0.01), the mica group was much lower than the model group (2.00±1.53 vs. 4.00±0.89, p<0.01). 2) Colonic tissues histological score: The histological score of the model group was much higher than the control group (8.17±2.99 vs. 1.33±1.03, p<0.01). Compared with the model group, the histological score in the mica group decreased significantly (3.83±1.27 vs. 1.31±2.09, p<0.01). 3) The level of Ang, ACE2, Ang1-7 in mice colonic tissues: The level of Ang, and Ang1-7 in the model group were increased compared with the control group (Ang,4.83±2.11 vs. 2.16±0.41, p<0.01; Ang1-7:2.0±0.63 vs. 0.13±0.14, p<0.05). But in the mica group the level of Ang, and Ang1-7 were significantly reduced compared with the model group (Ang,2.32±0.52 vs. 4.83±2.21, p<0.01; Ang1-7:1.04±0.56 vs. 2.0±0.63, p<0.01). Compared with the control group, the expression of ACE2 in colonic tissues from mice in the model group was increased (3.50±0.53 vs. 2.04±0.29, p<0.05), and in the mica group it was significantly increased than in the model group (5.13±1.84 vs. 3.50±0.55, p<0.05). 4) The expression of IL-17A in mice colonic tissues: The expressions of IL-17A in colonic tissues from mice in the model group and the mica group were significantly increased (6.93±0.44 vs. 0.65±0.03, p<0.01; 2.63±0.64 vs. 0.65±0.33, p<0.01). Meanwhile, the expression of IL-17A in the mica group was lower than in the model group (2.63±0.64 vs. 6.93±0.44, p<0.01). 5) Correlation analysis: Pearson’s correlation analysis showed that Ang, was moderately correlated with the mice colonic macroscopic damage index (r=0.52, p<0.05), and was highly positive correlation with the mice colonic histological score (r=0.909, p<0.01).

Conclusion: There is an imbalance between Ang, and ACE2, Ang1-7 in the TNBS-induced experimental colitis mice. And mice can reduce colonic tissues inflammation and damage.

Introduction: Inflammatory bowel diseases (IBD) is associated with an increased risk of colorectal cancer. However, the mechanism of immune signaling pathways linked to colitis-associated cancer (CAC) has not been fully elucidated. Tauroursodeoxycholic acid (TUDCA) exhibits anti-inflammatory and anti-cancer activities. The aim of this study is to investigate the role of TUDCA in the pathogenesis of CAC.

Aims and Methods: CAC was induced in mice using azoxymethane (AOM) and dextran sodium sulfate (DSS) administration, and TUDCA’s effect on tumor development was evaluated. HCT 116 and COLO 205 were treated with TUDCA or vehicle and then stimulated with tumour necrosis factor alpha (TNF-α). The expression of interleukin (IL)-8 was determined by real-time RT-PCR and ELISA, and IκBα phosphorylation and degradation was evaluated by immuno-blot assay. The DNA-binding activity of NF-κB was assessed by electrophoretic mobility shift assay (EMSA). Cell viability assays and real-time PCR of bcl-2, bcl-xl, MCL1, c-FLIP-L and VEGF were performed.

Results: TUDCA significantly attenuated the development of CAC in mice. Exposure to TUDCA resulted in reduced epithelial apoptosis and reduced levels of phospho-IκB kinase in the colon. In HCT 116 cells stimulated with TNF-α, TUDCA significantly inhibited IL-8 expression and suppressed TNF-α-induced IκBα phosphorylation and DNA-binding activity of NF-κB. Furthermore, in both HCT 116 and COLO 205 cells, TUDCA reduced cell viability and downregulated the expression of bcl-xl, MCL1, c-FLIP-L and VEGF.

Conclusion: These results demonstrated that TUDCA suppresses NF-κB signaling and ameliorates colitis-associated tumorigenesis, suggesting that TUDCA could be a potential drug for CAC.

Introduction: The gut mucosa is continuously exposed to a vast community of microorganisms, collectively defined as microbiota, establishing a mutualistic interaction, benefiting the host to adapt to the changing environment. Gut microbiota is acquired at birth, and its composition is relatively stable during the entire adult life. Intestinal dysbiosis, defined as a microbial imbalance of gut bacterial communities, can be caused by several factors, including bacterial infection, immunological dysregulation, aging, and lifestyle changes. A dysbiotic microbiota after antibiotic treatment imprints colonic iNKT and conventional T cells. Due to the strong correlation between composition of gut microbiota and immune system, understanding the mechanisms of gut microbiota modulation can provide important insights into the pathogenesis of inflammatory bowel disease.

Aims and Methods: We aimed to evaluate gut microbiota and adaptive immune system response change following anti-TNF-alpha therapy in murine dextran sulfate sodium (DSS) colitis. C57BL6 mice were fed for 5 days with 3% DSS in drinking water. At day 3 of DSS treatment, mice received intravenous administration of 5 mg Kg of infliximab (IFX), an anti-TNF alpha monoclonal antibody, or placebo. Further 2 groups of mice received IFX or placebo without DSS. Disease activity index (DAI) was scored daily using the 4 points Disease Activity Index (DAI). At day V and XI serum, colon, feces and mesenteric lymph node (MLN) were collected from each animal. Microorganisms belonging to Bacteroides, Clostridiales, Enterobacteriaceae and Fecalibacterium prausnitzii were assessed by FISH and qPCR following bacterial DNA extraction from feces. Th1, Th2, Th17 and Treg cell distribution in the MLN were evaluated by intracellular cytokine staining by flow cytometry.

Results: Anti-inflammatory species (Bacteroides, Clostridiales and Fecalibacterium prausnitzii) decreased during DSS-induced colitis and increased in fecal samples of IFX-treated colitis mice compared to control mice. Conversely, pro-inflammatory microorganisms belonging to Enterococcaceae genera increased during colitis and decreased after IFX treatment. Furthermore, in IFX-treated colitic mice, microbial changes are associated to an initial increase (day 5 of the colitis) in Treg cells and a consequent decrease (day 12 of colitis) in Th1, Th2 and Th17 cells. Similarly, healthy mice treated with IFX showed the same histological features, microbial and immune changes of untreated colitic mice.

Conclusion: Anti-TNF alpha treatment in experimental model of colitis improves disease activity trough changes in T cell subsets and in microbiota composition. Furthermore, the present study suggests that different components of the microbiota can distinctly influence the differentiation and accumulation of specific populations of immune cells. Further analysis on immune cells within mucosa will be necessary.

P0280 THERAPEUTIC POTENTIAL OF GLEPAGLUTIDE, A LONG-ACTING GLUCAGON-LIKE PEPTIDE-2 RECEPTOR AGONIST, IN A RAT MODEL OF RECURRENT INDOMETHACIN-INDUCED SMALL INTESTINAL INJURY. LAMINATION

J Skarbaliene1, C Thorkildsen1, M Berner-Hansen1, W Russell2
1Zealand Pharma A/S, Glostrup, Denmark
2Contact E-Mail Address: jsk@zealandpharma.com

Introduction: Glepaglutide (ZP1848) is a novel, long-acting GLP-2 receptor agonist that is currently in clinical development for the treatment of short-bowel syndrome. We have previously shown that treatment with glepaglutide in a rat model of indomethacin-induced small intestinal (SI) inflammation enhanced intestinal repair, as measured by increase in intestinal mass and plasma citrulline levels, and decrease in inflammatory markers. Aims and Methods: The aim was to determine whether pre- and continuous treatment with glepaglutide would attenuate the SI inflammation response in rats exposed to a second inflammatory episode. 2 cycles of SI inflammation were induced in male Wistar rats by indomethacin administration (7 mg/kg, s.c.) on day 0 and day 1 (primary challenge) and then again on day 18 and day 19 (secondary challenge). Rats were treated with glepaglutide (80 and 400 mmol/kg, s.c.) from day 0 to day 14 (pretreatment), or from day 0 to day 21 (continuous treatment). Groups of rats (n = 8/group) were sacrificed on days 15 and 22. Study endpoints were bodyweight (BW), jejunal and ileal mass/BW, SI length, and SI levels of alpha 1 acid glycoprotein (α1-AGP; ELISA kit, Life Diagnostics) and myeloperoxidase (MPO; ELISA kit, Hycult Biotechnology). Results: Pretreatment with glepaglutide (80, 400 mmol/kg) increased jejunal- and ileal mass/BW on day 15 (p < 0.001 for both dose levels vs Indomethacin group). The second indomethacin-induced SI inflammation episode was characterized by BW loss, increased jejunal and ileal mass/BW, decreased SI length, and increased SI levels of α1-AGP and MPO. Pre- (400 mmol/kg) and continuous treatment (80 mmol/kg) with glepaglutide prevented BW loss in animals after the second inflammatory episode (p = 0.001 for all comparisons vs Indomethacin group). In addition, both pre- and continuous treatment with glepaglutide (400 mmol/kg) significantly increased ileal mass/BW on day 22, but had no effect on jejunal mass/BW or Indomethacin group. Both treatment regimes dose-dependently counteracted the shrinking of the SI length, and decreased SI levels of inflammatory markers (α1-AGP and MPO) during the second phase of inflammation (day 22).

Conclusion: We have demonstrated that pre- and continuous treatment with glepaglutide protected the SI against the recurrent inflammatory episode. In addition, pretreatment with glepaglutide increased SI mass assessed prior to the induction of the second phase of inflammation, suggesting that this increase in SI mass may provide the SI with more resistance to the second inflammatory insult. In conclusion, glepaglutide may provide an attractive option for the treatment and/or prevention of the unpredictable course of inflammatory bowel disease.

Introduction: Several experimental data have highlighted the potential role of intestinal macrophages in the pathogenesis of Crohn’s Disease (CD). These macrophages present a defect in the control of CD-associated adherent-invasive E. coli (AIEC) replication, which could be linked to altered autophagy. Aims and Methods: We investigated the impact of several CD-associated sing gene nucleotide polymorphisms (SNPs) including those involved in autophagy on the ability of macrophages from CD patients to eliminate AIEC bacteria. Peripheral blood monocyte-derived macrophages (MDM) were obtained from 95 CD patients, 30 ulcerative colitis (UC) patients and 15 healthy subjects genotyped for CD-associated SNPs related to autophagy, especially IRGM (rs10065172) and ULK1 (rs12303764) and, infected with AIEC LF82 reference strain. Functional assay were performed on MDM after AIEC infection and/or after a short-term silencing of ULK1 gene. The numbers of intracellular bacteria were determined using gentamicin protection assay. IRGM, ULK1 and p62 protein expression was determined by western blot. Results: AIEC survival was increased within MDM from CD patients compared with MDM from UC patients or healthy subjects (p = 0.0019). MDM from CD patients failed to kill AIEC bacteria especially in patients harboring the CD-associated IRGM SNP (p = 0.045). In contrast, AIEC survival was decreased in MDM from patients with the CD-associated ULK1 SNP (p = 0.046). ULK1 expression, but not IRGM and p62, was increased in MDM from CD patients infected by AIEC bacteria compared to MDM from UC patients or healthy subjects (p = 0.0056) and are significantly correlated with the AIEC survival (p = 0.0309). In this line, ULK1 down-regulation within MDM limits the AIEC survival (p = 0.0018).

Conclusion: We confirmed that MDM from CD patients failed to eliminate AIEC bacteria compared to those of UC or healthy subjects. Our results highlight a role of CD-associated SNPs related to autophagy, IRGM and ULK1, on the ability of macrophages from CD patients to mediate AIEC bacterial clearance. At the protein level, our data suggested a role of ULK1, the cornerstone of autophagy initiation, to control AIEC bacteria within macrophages, in patients with CD. This protein could represent a potential new target to alter the interaction between macrophages and AIEC bacteria.

Contact E-Mail Address: georgios.mavroudis@vgregion.se

Introduction: Alterations in the immunopathogenesis in ulcerative colitis (UC) due to the natural disease course have been proposed but so far data are lacking. We therefore aimed to determine mucosal and systemic immune profiles at the time of diagnosis and after 10 years later in UC patients. Aims and Methods: Patients with UC provided serum and mucosal biopsies during a flare at the time of diagnosis and after 10 years of disease. The combination of these taxa into a microbial dysbiosis index showed a strong positive correlation with clinical disease severity and negative correlation with species richness. Conclusion: The dysbiosis of mucosa-associated microbiota was associated with disease phenotype, which could be partly restored after the induction of remission. We speculate that the trajectory of early microbiome changes may represent a predictive factor for relapse.

Disclosure: Nothing to disclose

P0284 CHARACTERISTICS OF MUCOSA-ASSOCIATED GUT MICROBIOTA DURING TREATMENT IN CROHN’S DISEASE

C He, H Wang, X Zhu, W Liao, Z Zhu
The First Affiliated Hospital of Nanchang University, Department of Gastroenterology, Nanchang, China

Contact E-Mail Address: hecong.1987@163.com

Introduction: The dysbiosis of gut microbiome seems relevant to the pathogenesis of Crohn’s disease (CD), with differences between patients with CD and healthy subjects (HS) both in composition. However, it is not clear how the gut microbiota changed from active CD to remission after treatment. Aims and Methods: The aim of this study was to characterize the dynamic alterations of mucosa-associated intestinal microbiota in CD patients after induction of remission. 16S rRNA sequencing approach was applied to determine the structures of microbial communities in mucosal samples including terminal ileal, ascending colon and descending colon. The composition and function of mucosa-associated gut microbiota were compared between paired samples from CD patients at pre and post induction stage during disease treatment. Results: There were no significant differences in microbial structure among the three anatomical sites within individuals. Compared to active disease, the alpha diversity of CD in remission was increased and approximately up to the level of HS. The principal coordinate analysis revealed that samples of active CD clearly separated from those in remission which clustered close to HS. 42 genera were identified to be differentially abundant between active and quiescent CD with a loss of Faecalibacterium and a gain of potential beneficial bacteria including Lactobacillus, Akkermansia, Roseburia, Ruminococcus and Lachnospira after the induction of remission. The combination of these taxa into a microbial dysbiosis index showed a strong positive correlation with clinical disease severity and negative correlation with species richness.

Introduction: Alterations in the immunopathogenesis in ulcerative colitis (UC) due to the natural disease course have been proposed but so far data are lacking. We therefore aimed to determine mucosal and systemic immune profiles at the time of diagnosis and after 10 years later in UC patients. Aims and Methods: Patients with UC provided serum and mucosal biopsies during a flare at the time of diagnosis and after 10 years of disease. mRNA gene expression in biopsies was analyzed using the Qagent RT Profile PCR Arrays Antibacterial response and T Helper Cell Differentiation with 84 genes per array, in total 152 unique genes. Serum samples were analyzed using Olink Proseek Inflammation panel including 92 proteins (normalized protein expression (NPX)), but only the 43 proteins related to digestive tract were included in the analyses. Logarithmic data were analyzed in SIMCA using OPLS-DA to identify parameters discriminating between early and late disease, implementing a Variable Importance for the Projection (VIP) cut-off > 1. Identified parameters were used for univariate analysis and false discovery rate analysis. Data are
presented as fold change of means for mRNA analyses and median (interquartile range) for protein expression.

**Results:** The study included 15 UC patients (mean age 48 years after 10 years of disease, 60% males) where 8 had extensive, 5 left-sided disease and 2 proctitis. No patient had ongoing treatment with corticosteroids or biologics (2 were previously treated). 3 patients currently used Azathioprine and 10 oral aminosalicylates. When comparing early and late disease, the mRNA profiles in biopsies discriminated the groups and showed high predictability for oral aminosalicylates. When comparing early and late disease, the mRNA profile was detected during late compared to early disease. Additionally, a fold decrease of the Th1-associated genes TNF (0.66, q = 0.003) and SOCS1 (0.66, q = 0.004) was found during late compared to early disease. Furthermore, IL-8 (7.4 (6.9–7.9, V.9) vs. 8.9 (7.1–14.5, N.PX)) and MCP3 (2.2 (1.9–2.6, V.8) vs. 2.8 (2.3–28.0, N.PX), important for recruitment of neutrophils and monocytes, and TNSF14 (6.7 (5.4–7.2) vs. 7.6 (6.5–8.3, N.PX), CCL20 (4.7 (4.4–5.4) vs. 5.8 (5.5–6.2, N.PX) and CCL28 (1.4 (1.2–1.6) vs. 1.6 (1.5–1.9, N.PX)) associated with lymphocyte homing were decreased during late as compared to early disease.

**Conclusion:** Mesosalic and inflammatory systemic profiles differ between early and late disease in UC patients with active disease, with a change from a Th Helper 1 to a Th Helper 2 cell driven disease. Improved understanding of the variation in immune pathogenesis due to the natural disease course is important to guide individualized treatment decision-making.

**P0284 LOW LEVEL OF KNOWLEDGE OF PREGNANCY-RELATED ISSUES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE IN POLISH POPULATION**

M Kukulska

1 Wroclaw Medical University, Wroclaw, Poland

Contact E-Mail Address: monika.kukulska@gmail.com

**Introduction:** Inflammatory bowel diseases (IBDs) belong to the group of chronic diseases, significantly increase the risk of surgery, colorectal cancer and often influence the reproductive decisions of the patients, may influence their personal life choices regarding family planning and having children.

**Aims and Methods:** The aim of the work was to assess the knowledge of female patients with IBD regarding pregnancy and fertility issues in respect of the disease. The goal of the work was also to educate the patients. The examinations were based on validated test CCPKnow (Crohn’s and Colitis Pregnancy Knowledge Score). The study included 120 women at the age of 18 to 74, including 86 women at the age up to 45 years old, 59 women with CD (Crohn’s disease) and 61 women with UC. The patients were endoscopically and histologically healthy and served as controls. The IBD patients were divided into three groups: UC, CD and IBD patients with active disease. The difference in the level of knowledge assessed by means of CCPKnow test was estimated to 6.9 of 17 points possible. Through the analysis was also made an estimate of the post-inflammatory restoration of the mucosa (1). However, the role of TCs in human pathophysiological conditions is still an open question.

**Aims and Methods:** The aim of the present prospective study was to test the hypothesis that the count of colonic TCs in patients with inflammatory bowel disease (IBD) is altered compared to healthy controls (controls). Endoscopic colonic mucosal biopsies from 38 individuals were included in the study; 14 patients with Ulcerative Colitis (UC) in clinical and endoscopic remission (total Mayo score < 2 and no sub score > 1), 9 with clinical and endoscopic active UC (total Mayo score > 2 and Mayo endoscopic sub score > 1), 10 with colonic Crohn’s Disease (CD) in endoscopic and histological remission (1 had slight inflammation of the terminal ileum), 8 with endoscopically and histologically quiescent colon CD, and 7 with endoscopically and histologically quiescent UC.

**Disclosure:** Nothing to disclose

**Introduction:** The gastrointestinal tuft cells (TCs) have recently been revealed as parasite-sensing cells in rodents. TCs play a key role in initiation of a type-2 immune response and lead to polarization of the immune system. The gut microbiota is known to play a key role in the post-inflammation restoration of the mucosa (1). However, the role of TCs in human pathophysiological conditions is still an open question.

**Aims and Methods:** The aim of the present prospective study was to test the hypothesis that the count of colonic TCs in patients with inflammatory bowel disease (IBD) is altered compared to healthy controls (controls). Endoscopic colonic mucosal biopsies from 38 individuals were included in the study; 14 patients with Ulcerative Colitis (UC) in clinical and endoscopic remission (total Mayo score ≤ 2 and no sub score ≤ 1), 9 with clinical and endoscopic active UC (total Mayo score > 2 and Mayo endoscopic sub score > 1), 10 with colonic Crohn’s Disease (CD) in endoscopic and histological remission (1 had slight inflammation of the terminal ileum), 8 with endoscopically and histologically quiescent colon CD, and 7 with endoscopically and histologically quiescent UC. No contraceptive use was assessed by means of CCPKnow test. The difference in the level of knowledge assessed by means of CCPKnow test was estimated to 6.9 of 17 points possible. Through the analysis was also made an estimate of the post-inflammatory restoration of the mucosa (1). However, the role of TCs in human pathophysiological conditions is still an open question.

**Conclusion:** The gastrointestinal tuft cells (TCs) have recently been revealed as parasite-sensing cells in rodents. **LOCUS REGULATORY B CELLS CONTRIBUTE TO ALLOCUTE THE ACUTE COLITIS IN CD19<sup>+</sup> MICE**

X Li, J Tan, Q Xue, Y Li, J Wang
Peking University People’s Hospital, Department of Gastroenterology, Beijing, China

**Contact E-Mail Address:** lixialiy@163.com

**Introduction:** Epidemiological studies showed that there was an inverse relationship between H. pylori (H pylori) infection and the incidence of inflammatory Bowel Diseases (IBD). It was confirmed that CD4<sup>+</sup>+CD25<sup>+</sup>+Foxp3<sup>+</sup> Treg cells could protect mice from colitis. Our previous study showed that H. pylori infection induced the expansion of regulatory B cells (Breg) ahead of the Treg cells.

**Aims and Methods:** In this study, we investigated the effect of Breg cells on acute colitis induced by dextran sulphate sodium (DSS). SPP CD19<sup>+</sup> mice were utilized. 1x10<sup>6</sup> Breg or B cells or equal PBS were adoptive transferred to the CD19<sup>+</sup> mice via the tail vein. Twenty-four hours later, acute colitis was induced by 3% DSS. Duplicate sigmoidal biopsies were cultivated without (none) or with 1.6 mM butyrate. mRNA gene expression was analyzed using the Qiagen RT2 Profiler PCR Arrays.

**Results:** MKL1-Tg mice displayed spontaneous colon shortening and rectal prolapse. Scattered cryptitis was observed among the colons. Flow cytometric and quantitative RT-PCR analyses revealed that, in MKL1-Tg mice compared to littermate controls, the proportion of LPMac was decreased and had an altered inflammatory phenotype indicative of impaired anti-inflammatory properties. MKL1 also orchestrates macrophage polarization. Of note, overexpression of MKL1 impacts transcriptional activities of NF-κB p65 and PPARγ. Furthermore, MKL1-Tg mice had higher susceptibility to DSS-induced colitis, which was accompanied with prominent B cells infiltration and follicle formation.

**Conclusion:** Our observations indicated that MKL1 crucially contributes to the development of colitis via the regulation of the function of macrophages, suggesting that it may be a potential therapeutic target for the prevention of IBD.

**Disclosure:** Nothing to disclose.

**PO287 IMPAIRED BUTYRATE INDUCED ANTI-INFLAMMATORY IMMUNE REGULATION IN LAMINA PROPRIA CELLS FROM PATIENTS WITH ACTIVE ULCERATIVE COLITIS**

M.L Magnusson, S Isaksson, L Öhman
University of Gothenburg, Dept. of Microbiology and Immunology, Inst. of Biomedicine, Gothenburg, Sweden

**Contact E-Mail Address:** maria.magnusson@microbio.gu.se

**Introduction:** Modulation of the gut microbiota has emerged as a therapeutic option for patients with ulcerative colitis (UC), yet with modest effects. Microbial dysbiosis and reduced levels of short-chain fatty acids such as butyrate have been identified as key components of the disease and butyrate is known to have anti-inflammatory properties.

**Aims and Methods:** Here we aimed to determine and compare immunological effects and cytokine profile (IL-1β) from UC patients with active disease and non-inflammatory control (CTR) patients.

**Results:** Duplicate sigmoidal biopsies were cultivated without (none) or with 1.6 mM butyrate (but) for 6h after which biopsies were collected for RNA purification. mRNA gene expression was analyzed using the QuanTr RT<sup>®</sup> Profiler PCR Arrays Antibacterial response and Innate and Adaptive Immune Responses with 84 genes per array, in total 135 unique genes. Logarithmic data were analyzed using principal component analysis (PCA) and orthogonal partial least squares discriminant analysis (OPLS-DA) with a cut off for Variable Importance for the Projection >1.2. Identified parameters were subject to univariate analysis and false discovery rate analysis and evaluated using Ingenuity Pathway Analysis (IPA). Gene expression data are presented as fold change (IC) of means on a log<sub>2</sub> scale where log<sub>2</sub>FC = 1 and −1 define a 2-fold increase and decrease, respectively.

**Results:** The study included 8 CTR patients (4 males, age 54 (24–84), median (range)) and 8 patients with UC (6 males, age 38 (32–74)) with a disease duration of 7 (<1–47) years. All UC patients had active disease with endoscopic Mayo score >7 (n=8), CTR patients had Mayo score 0. Current treatment for UC patients was 5ASA (n=5), 5ASA and thiopurines (n=1), corticosteroids (n=1) and no treatment (n=1).

**Conclusion:** Our data suggests that macrophage polarization by MSC is affected by the cell quality and that passaging of cell could impair its immunomodulatory effects and tumour necrosis factor receptor superfamily member 13b (Tnfrsf11b).

**Disclosure:** Nothing to disclose.
P0290 DOES ASTHMA INCREASE THE RISK OF INFLAMMATORY BOWEL DISEASE? A META-ANALYSIS OF CASE-CONTROL AND COHORT STUDIES

1Kanto Central Hospital, Department of Endoscopy, Tokyo, Japan
2Kishiwada Tokushukai Hospital, Department of Gastroenterology, Kishiwada, Japan

Contact E-Mail Address: hirokinya@hara@gmail.com

Introduction: There have been several studies that assessed the association between asthma and inflammatory bowel disease (IBD) including Crohn’s disease (CD) and ulcerative colitis (UC). The positive association may be explained through the hygiene hypothesis, which postulates that a reduction in the frequency of infections contributes directly to the increase in the frequency of autoimmune and allergic diseases.

To provide a quantitative assessment of the association of asthma with subsequent IBD risk, we conducted a meta-analysis of observational studies.

Aims and Methods: We identified studies by searching the PubMed databases through February 2018 and by searching bibliographies of relevant articles. Included studies reported IBD as the primary outcome and evaluated asthma before diagnosed with IBD. We included case - control studies or cohort studies published as original articles; cross-sectional, ecological, and prevalence studies were excluded.

Results: A total of 7 observational studies were included in our meta-analysis. Asthma was associated with an increased risk of CD (summary OR 1.45, 95% CI: 1.30–1.61) and UC (summary OR 1.29, 95% CI: 1.02–1.64).

Conclusion: This meta-analysis demonstrates that asthma is associated with an increased risk of both CD and UC. Further prospective studies are required to confirm the validity of these observations.

Disclosure: Nothing to disclose.

P0291 THE PREVALENCE OF GASTROINTESTINAL CANCERS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE - A DANISH NATIONWIDE COHORT STUDY

P Weimers, D Ankersen, J Burisch, P Munkholm
North Zealand University Hospital, Department of Gastroenterology, Frederiksund, Denmark

Contact E-Mail Address: zld051@alumni.ku.dk

Introduction: Inflammatory Bowel Disease (IBD), mainly represented by Crohn’s Disease (CD) and Ulcerative Colitis (UC), is known to be associated with an elevated risk of gastrointestinal (GI) cancer. The pathogenesis is poorly understood, but risk factors seem to be longstanding disease as well as extensive disease and high degree of inflammation. However, the reported magnitude of the risk in IBD patients is still inconsistent and the long-term effects of newer treatment options on the development of cancer have not been investigated thoroughly.

Aims and Methods: To estimate the prevalence of GI cancer development in a Danish nationwide cohort of IBD patients, overall cancer as well as neoplasms located to the small bowel, anus/anal canal, liver, bile ducts and pancreas were more prevalent compared to the reference individuals. There was a significant difference in the prevalence of colorectal cancer between reference individuals and IBDU patients, but not compared to the overall IBD cohort.

Conclusion: In a Danish nationwide cohort of IBD patients, overall cancer as well as neoplasms located to the small bowel, anus/anal canal, liver, bile ducts and pancreas were more prevalent compared to the reference individuals. There was a significant difference in the prevalence of colorectal cancer between reference individuals and IBDU patients, but not compared to the overall IBD cohort.

Introduction: Acute severe attack of ulcerative colitis (ASUC) can occur in 12 to 25% of UC patients. This is a challenging and life threatening in elderly patients. Evolution of ASUC in late onset UC diagnosed after the age of 60 years is unknown.

Aims and Methods: The aim of this study was to describe clinical presentation, treatment and prognosis of ASUC in a cohort of late onset UC.

Patients and methods: In a Northern France population-based cohort, we identified 472 patients aged >60 years at UC diagnosis ulcerative colitis (UC). These patients were followed for a median time of 6.2 years. Among these patients, those hospitalized with an ASUC according to the Truelove’s criteria were analyzed. Clinical presentation, comorbidities (Charlson index), treatment and surgery needs as well as postoperative complication and mortality were recorded.

Results: 23 patients (5%) including 14 men were included. ASUC occurred at diagnosis in 12 patients (52%) and during the first year of follow-up in 19 patients (83%). The Charlson comorbidity score was ≥ 3 in 96% (n=22) and ≥ 5 in 52% (n=12) of the cases. First-line treatment was intravenous corticosteroid (64%, n=14), colectomy (22%, n=4) or exclusive artificial nutrition (24%, n=5). No patient received second line medical treatment ciclosporin or infliximab. Among the 18 operated patients, median time between admission for severe acute colitis and intervention was 15 days (Q1 = 9, Q3 = 39). Surgery was a subtotal colectomy with double stoma in 13 cases, a partial colectomy in 3 cases, total colectomy in 1 case and a stomy alone in 1 case. Stoma were definitive in 69% (n=9) of cases. 1 or more postoperative complications occurred in 6 patients (26%) i.e. renal insufficiency (n=4), thromboembolic event (n=4),...
septic shock (n=2). 5 patients (22%) died, of which 4 after surgery, leading to a 3-month survival rate of 75% (IC95%: 58–97%) (Figure 1).

Conclusion: In this population-based study conducted in the prebioterapia era ASUC in elderly onset UC patient was rare but particularly severe requiring surgery in 74% of patients and life-threatening with a mortality rate close to 2% in 3 months. Management of these severe patients in referral centers is mandatory.

P0294 SMOKING REMAINS A MAJOR CONTRIBUTOR TO THE BURDEN OF CROHN’S DISEASE IN IRELAND AND WARRANTS THE DEVELOPMENT OF A SPECIFIC TARGETED SMOKING CESSATION INTERVENTION

A.R Douglas1, X Mohez2, Z San1, I Cotter2, H Scow2, C Gallagher2, B Ryan4, D McNally3,5

5Tallaght Hospital, Gastroenterology, Dublin, Ireland

Contact E-Mail Address: douglaar@tcd.ie

Introduction: Approximately 15,000 people in Ireland have Crohn’s disease (CD) and a high prevalence of smoking. Previous data suggest that smokers are twice as likely to develop CD and active CD smokers have a higher risk of relapse, hospital admissions, steroid therapy and surgery. Despite this, many Irish CD patients continue to smoke perhaps due to lack of knowledge and awareness.

Aims and Methods: To determine current smoking rates and the impact of smoking on CD severity and to assess patient knowledge and awareness of the risks associated with smoking. Following ethical approval, a prospective case control study of Irish CD patients' and age and sex matched non IBD GI patient controls was undertaken. A self-assessment questionnaire was employed to assess smoking habits, basic demographics and education status overall as well as disease characteristics and awareness of the impact of smoking in the CD cohort. Groups were compared using a Chi²-test, p of less than 0.05 were considered statistically significant and odd ratios were calculated where appropriate.

Results: To date 139 questionnaires have been returned, 56 from CD patients and 83 from Controls. The mean age was 47 years (range 19–80) and 62 (47%) were females. The smoking status of the groups was 33% (n=46) vs 44% (n=36) respectively (p=0.3). Rates of smoking were 58% (n=37) vs 59% (n=33) respectively (p=0.8). In a multiple logistic regression model, smoking was a significant risk factor for CD (OR 1.91, 95% CI 1.1–3.3). In fact, active smokers were twice as likely to develop CD (OR 2.2, p=0.05). Current smokers also had a higher BMI (mean 25.6 vs 24.8 kg/m², p=0.01) and higher HBI (mean 7, RR 2.2, p=0.02). There was no difference in steroid use between the groups. Only 41% (13/32) of our CD cohort thought smoking was a significant risk factor for BD. While only 28% (9/32) thought smoking was a risk factor for surgery while just 16% (5/32) thought smoking cessation could significantly decrease the severity of their disease.

Conclusion: Disturbingly, smoking rates remain high in our Irish CD population, with a negative impact on disease severity and need for surgery. Surprisingly few CD patients were aware of the negative impacts of smoking and the potential benefit of cessation. Emphasizing an urgent need for a specific targeted smoking cessation intervention.

P0295 OCULAR MANIFESTATIONS IN A TERTIARY IBD CENTER: BETTER TO KEEP AN EYE ON

G Rizzati1, S Gerardi1, C Manganelii1, V Peitot1, C Graziani1, G Hollar1, L.R Lopetuso1, E Schiavoni1, D Napolitano1, M Pizzoferrato1, L Laterza1, G Ianiro1, A Cipresso1, A Papa1, A Armuzzi2, A Gasbarrini1, F Scalfaretti1, 2
1“A. Gemelli” University Policlinic Foundation - Catholic University of Sacred Heart, Gastroenterological Area, Rome, Italy
2“A. Gemelli” University Policlinic Foundation - Catholic University of Sacred Heart, Head & Neck Department-Ophthalmology Division, Rome, Italy
3Adelaide and Meath Hospital, Gastroenterology, Dublin, Ireland
4“A. Gemelli” University Policlinic Foundation - Catholic University of Sacred Heart, Complessio Integrato Columbus, Rome, Italy

Contact E-Mail Address: gianenrco.rizzati@gmail.com

Introduction: Extra-intestinal manifestations (EIM) are common in inflammatory bowel disease (IBD) occurring in up to 50% of patients, while ocular manifestations are reported in 0.3% to 13.9% of the cases. Reported data, however, mostly rely on not recent population based studies. In fact, the few available prospective studies, suggest a much higher occurrence of ocular diseases, ranging from 29% to 71%.

Aims and Methods: The aim of the study was to assess the prevalence of ocular disease in a cohort of IBD patients followed in tertiary referral Italian center. IBD patients followed at our center were consecutively enrolled in the study. Enrolled patients underwent ocular evaluation including assessment of visual acuity, examination of fundus oculi and anterior ocular segment as well as a measurement of intraocular pressure, Schirmer’s test and break up time test, when appropriate.

Results: A total of 193 IBD patients were enrolled in the study, 54.9% females and 45.1% males, 47.7% CD, 43.5% UC, and 8.8% indeterminate colitis, 35.7% of patients had a moderate-severe activity of disease, 39.4% were under steroid therapy, 35.8% were under anti-TNFalpha and 64.3% were taking mesalamine.

Overall, any ocular disease was identified in 46.1% of enrolled patients, 17.1% CD and 23.3% UC and 5.2% IC. The most common ocular disease was dry eye (12.4%). At multivariate analysis use of mesalamine (OR 2.3, 95% CI 1.1–5.0), steroids (OR 3.6, 95% CI 1.1–11.8) and moderate-severe activity of disease (OR 5.1, 95% CI 2.3–11.1) were all correlated with an increased risk of ocular disease. Characteristics of Ocular manifestations in IBD patients are more frequent than reported especially in referral center. Patients under treatment with mesalamine or steroids and with a moderate-severe disease activity might benefit of an ophthalmological evaluation.

4“A. Gemelli” University Policlinic Foundation - Catholic University of Sacred Heart, Direzione Sanita, Rome, Italy
3“A. Gemelli” University Policlinic Foundation - Catholic University of Sacred Heart, Complessio Integrato Columbus, Rome, Italy

Contact E-Mail Address: gianenrco.rizzati@gmail.com

Introduction: Inflammatory bowel disease (IBD) patients are at higher risk to suffer from colorectal cancer. While the association between ulcerative colitis (UC) and colorectal cancer is well defined, the risk for Crohn's disease (CD) is less defined. Similarly, little information exists on extra-intestinal tumors in different settings of patients.

Aims and Methods: The aim of the study was to assess occurrence of malignancies in IBD patients admitted to the hospital. All patients admitted for CD or UC to Policlinico-“A. Gemelli” between 2000 and 2013 were identified using ICD-9-CM codes for IBD. A review of gastrointestinal or extra-intestinal cancer was assessed for every patient analyzing ICD-9-CM codes. Demographic characteristics of admitted patients were also recorded.

Results: A total of 3347 patients were admitted for an IBD between 2000–2013, in 2000 9.6% (n=125) vs 2013 29.7% (n=992). Malignant tumors, at any site, were more frequent in UC than in CD (7.3% versus 2.7%, respectively; p<0.05). Median age at admission was 44.0 years for patients without a diagnosis of tumor and 63.8 years for those with a diagnosis of cancer. The occurrence of colon and rectal cancer was 1.7%, with 81% cases affecting UC patients. The most frequent extra-intestinal malignancies were prostate cancer and myeloproliferative disorders. Colon and rectal cancer accounted for 59.8% of all gastrointestinal cancer.

Conclusion: About 5% of admitted IBD patients presented a cancer diagnosis. Higher cancer occurrence was observed in UC and in older patients, with a median age of about 60 years and more frequently in men. Colorectal cancer occurrence in UC was about 2%.
Results: Sera were available from 342 and 272 UC patients and 159 and 135 CD patients at the 10 and 20 year follow-up, respectively. The proportions of patients positive for the analyzed antibodies at the 10 and 20 year follow-up are presented in table 1. As previously shown, ASCA was more prevalent in CD than UC and in complicated CD behavior vs. inflammatory CD behavior at the 10 year follow-up. The status of ASCA on the other hand, changed significantly. These findings indicate that ASCA IgA remained stable from 10 to 20 year follow-up. The status of ASCA IgG on the other hand, changed significantly. These findings indicate that ASCA IgG for patients with both UC (p < 0.001) and CD (p < 0.001).

Conclusion: In a population-based inception cohort the status of pANCA and ASCA have been stable from 10 to 20 years. At the 10 and 20 year follow-up visits, the following panel of antibodies was analyzed in serum: pANCA, ASCA IgA and ASCA IgG. All analyses were performed at Prometheus Laboratories Inc. (San Diego, CA). Changes in antibody status within individuals from 10 to 20 years were assessed using Wilcoxon signed ranks test.

Disclosure: Sera were analysed by Prometheus laboratories free of charge.

P0298 INCIDENT CANCER IN INFLAMMATORY BOWEL DISEASE: CHARACTERIZATION AND RISK FACTORS IN A PROSPECTIVE MULTICENTER NESTED CASE-CONTROL IG-BD STUDY AT 6 YEARS

I Biancone1, A Armuzzi2, M.L. Sciraboni3, F Castiglione4, R D’Inca5, M Daperno6, C Papi7, M Vecchi8, W Fries9, G Riegler10, P Alvisi11, S Renna12, M Daperno6, C Papi7, M Vecchi8, W Fries9, G Riegler10, P Alvisi11, S Renna12

Introduction: Serological biomarkers in inflammatory bowel disease (IBD) predict complicated disease are warranted. Several microbial antibodies and auto-antibodies have been associated with IBD and especially ASCA and PANCA have been proposed as potential biomarkers. Studies have shown that their presence might vary over time thus their clinical impact is still discussed. Long term studies of ASCA and pANCA stability have not been performed in population-based cohorts.

Aims and Methods: The aim of the present study was to investigate potential change in antibody status over time by analysing a panel of relevant serum antibodies at 10 and 20 years after disease onset in a population-based inception cohort of IBD patients (the IBSEN cohort). The IBSEN cohort is an inception cohort of patients diagnosed with IBD between 1990 and 1994. The patients have been followed prospectively for 20 years. A total of 228 UC patients and 113 CD patients, sera were available at both time points. The antibody status within individuals changed significantly for ASCA IgG for patients with both UC (p < 0.001) and CD (p < 0.001).

Conclusion: In a population-based inception cohort the status of pANCA and ASCA have been stable from 10 to 20 years. At the 10 and 20 year follow-up visits, the following panel of antibodies was analyzed in serum: pANCA, ASCA IgA and ASCA IgG. All analyses were performed at Prometheus Laboratories Inc. (San Diego, CA). Changes in antibody status within individuals from 10 to 20 years were assessed using Wilcoxon signed ranks test.

Disclosure: Sera were analysed by Prometheus laboratories free of charge.

**Introduction:** The experience of patients with health care has been related to important outcomes (1). Aims and Methods: In this work we describe the perception of inflammatory bowel disease (IBD) patients on their experience with chronic health care in Spain through IEXPAC, a validated questionnaire, and the influence of demographic and health care-related factors. The IEXPAC scale (“Instrument to Evaluate the EXperience of PAtients with Chronic diseases”) was developed and validated in Spain by health care professional and social organizations, experts in quality of health care and chronic patients (2,3). It is structured in 12 items with Likert responses from ‘always’ to ‘never’, yields an overall score from 0 (worst) to 10 (best experience), and allows identifying health care areas needing improvement. 3 sub-scores derive from the scale: A) productive interactions (items on patient-health care professionals relationship), B) self-care (on patients’ ability to self-care) and C) new relational model (on the use of new technologies and contact with other patients). Consecutive IBD patients from 25 Spanish clinics completed the IEXPAC scale by pre-paid mail. Bivariate comparisons and a multivariate analysis were made to explore the association between scores and demographic and health care-related characteristics.

**Results:** 575 patients received the survey, 341 (59.3%) returned it (mean age 47 years, 48% women). Mean overall score was 5.9 (SD 2.0), sub-scores were: productive interactions: 7.7 (2.3); self-care: 6.9 (2.4); new relational model: 2.2 (1.8). Sex by age, sex and degree of education (except new relational model, better in younger and in those with higher education level). Experience score was better in patients followed-up by the same physicians (score 6.0 [1.9]) vs different physicians (5.0 [2.1], p = 0.002), if there was follow-up by a nurse (score 6.2 [2.1]) vs no follow-up by a nurse (5.6 [1.8], p < 0.001) and in those with lower number of medications (p = 0.010). Patients treated with subcutaneous/intravenous (SC/IV) drugs scored higher in the ‘productive interactions’ sub-score (p = 0.052). Multiple linear regression models (table) showed that being followed up by the same physician or by a nurse, and being treated with lower number of medications or with SC/IV drugs were independently associated to better overall experience scores.

**Conclusion:** Through IEXPAC, IBD patients identified important factors that can improve their experience with health care, like having the same physician as reference in the clinic and being followed-up by a nurse. Lower number of treatments was also associated to better experience and treatment with SC/IV drugs to higher ‘productive interactions’ sub-score, maybe in relation to a more personalized care.

**Disclosure:** This study was funded by Merck Sharp & Dohme of Spain and endorsed by the Spanish association of patients with Crohn’s disease and ulcerative colitis (ACCU). We thank the participating patients for providing this valuable information by completing the survey. Marta Mosquera, Nadia Soto, Berta Julià and Luis Cea-Calvo are employees at Medical Affairs, Merck Sharp & Dohme of Spain

Contact E-Mail Address: valerie.pittel@chuv.ch

**Introduction:** Complementary and alternative medicines (C&AM) may be defined as treatments that fall outside of conventional healthcare. Patients with IBD often turn to CAM, mainly without discussing it with their physician. We repetitively collect information on patient-reported CAM use between 2007 and 2016. Aims and Methods: 1) to assess main categories of patient-reported CAM used by IBD patients, with CAM use increasing among women (OR 1.5; p = 0.001).French-speakers (OR 1.5; p = 0.001) and lower with increased IBD QoL score.

**Results:** 21.7% to 29.3% of patients over years. Types of CAM were natural products and biologically based therapies (range: 6.9% to 11.9%), change in life habits (6.2% to 11.2%), whole medical systems and traditional medicines (5.8% to 9.6%), mind-body interventions (3.2% to 7.7%), body-based interventions (3.5% to 4.6%) and energy therapies (1.9% to 4.6%). When looking to the history of CAM use by patients in 2016, we found that 41.9%/44.4% of CD/UC patients used > 1 CAM reported from 2007-2016).

**Conclusion:** Positive coefficients mean better experience (higher IEXPAC score). Multivariate logistic regressions were performed to search for factors associated with CAM use (i.e. > 1 CAM use differed between UC and CD. Some of them seemed to be linked to relieving articular and musculoskeletal pain or improving IBD-specific or mental QoL.

**Disclosure:** The Swiss IBD cohort started in November 2006. At enrollment and on a yearly basis, patients were asked to complete self-reported questionnaires. CAM were collected using a list of previously identified CAM1,2 and a free text option. Additional clinical and patient-reported data collected within the framework of the cohort was used to characterize CAM users. For descriptive purposes, we classified CAM using recommendations of the US National Center for Complementary and Integrative Health (NCCIH). Changes in life habits (e.g. diet and sportive activities) was taken as an additional category. Dietary and nutritional supplements were not assessed here. Multivariate logistic regressions were performed to search for factors associated with CAM use (i.e. > 1 CAM use).

P0301 FECAL CALPROTECTIN MAY BE A SENSITIVE BIOMARKER IN ASSESSMENT OF HISTOLOGIC DISEASE ACTIVITY IN PATIENTS WITH ULCERATIVE COLITIS

Introduction: In patients with ulcerative colitis (UC) histological remission leads to better outcome, whereas presence of histological inflammation in quiescent disease is risk factor of future relapses. Fecal calprotectin (FCP) turned to be good biomarker in assessment of endoscopic and clinical disease activity.

Aims and Methods: The aim was to explore the association of FCP with histologic disease activity.
82 patients with UC from a single tertiary IBD Centre were enrolled in this prospective, observational study. Mayo endoscopic sub-score was used to evaluate an endoscopic activity. For the assessment of histological activity, Geboes’s, Nancy’s and Robarts’s score were used. Active (structural changes, the presence of polymorphonuclear leukocytes with cryptitis and crypt abscesses, and erosions or mucosal ulcers) and chronic inflammations were estimated. Histologic remission was defined by Geboes score < 3.1 or Nancy’s index ≤ 1 or Robarts’s index < 6. Basal plasmodicytosis, as a predictor of relapse, was described as well. Buhlmann rapid test was used to determine FCP using cut off level of 100 μg/g. Statistical analysis was carried out using SPSS 20.0 (Chicago, IL).

Results: 38% (31/82) of patients were in endoscopic remission while 33% (27/82) achieved histological remission. Statistically significant association was observed between FCP and histological indicators of active inflammation: a. structural changes p = 0.001, CI ± 8.5; b. presence of the presence of polymorphonuclear leukocytes with cryptitis and crypt abscesses p < 0.001, CI ± 10.6; c. presence of erosion and mucosal ulcers p < 0.001, CI ± 6.2, as well as with basal plasmodicytosis (p < 0.001, CI ± 6.4). The association with chronic inflammation was not observed (p = 0.002, CI ± 9.37). The correlation was found between FCP and all 3 scores with the strongest for Nancy index (r = 0.538- Spearman correlation). The correlation with Robarts score (r = 0.505- Spearman correlation) or Geboes (r = 0.382- Spearman correlation) were slightly lower.

Conclusion: Fecal calprotectin may be a good, sensitive, noninvasive biomarker in the assessment of histologic disease activity and point out a forthcoming relapse. This association with validated histologic score may even enhance the significance of FCP in clinical practice in the future.

Introduction: This study aimed to investigate the relationship between ARE(Arylesterase) and PON-1(Paraoxonase-1) levels in ulcerative colitis (UC) patients and the difference in these levels in UC patients in comparison to the control group.

Aims and Methods: The study population consisted of 66 (73.3%) UC patients and 24 (26.7%) healthy individuals as the control group. The UC patients and the control group were compared in terms of PON-1 and ARE levels as oxidative stress markers. The UC patients were also grouped according to Mayo UC activity scores and the differences in their PON-1 and ARE levels were assessed.

Results: 37 (56.1%) of 66 UC patients included in the study were male and 29 (43.9%) were female. The mean age in the control group was 42.2 ± 12.8 years (age range: 17-66 years). Most of the patients in the ulcerative colitis (UC) group used a combination of oral and rectal mesalamine treatments (20 patients, 33.3%). Most of the patients in the UC group had left-sided colon involvement (30 patients 45.5%). The mean arylesterase (ARE) level in the UC group was 786.32 U/L; the mean ARE level in the control group was 919.56 U/L. The ARE level was higher in the control group than the UC group, and this difference was statistically significant (p = 0.017). The mean paraoxonase-1(PON-1) value in the UC group was 264.14 U/L; the mean PON-1 value in the control group was 316.64 U/L. This difference was not statistically significant (p = 0.33).

When analysed based on gender, there was no difference in PON-1 levels (p = 0.23) and ARE levels (p = 0.98) between males and females in the UC group. When the Hb value was lower (equal and less than 10 mg/dl) and higher (higher than 10 mg/dl), the ARE value was statistically higher in the group with a high Hb value (p = 0.016). When assessed in terms of the Mayo Disease Activity Index (DAI) and Rachmilewitz Colonoocscopic Activity (Group A: ≤6 and 7 ≥ Group B) scores, no statistical difference was found between the ARE and PON-1 values for UC patients in Group A and Group B.

The ARE values of 66 UC patients were found to be negatively correlated with their white blood cell counts (r = -0.29; p = 0.03). In our study, ARE and PON-1 values were positively correlated in the UC group (r = 0.27; p = 0.026). Correlations between ARE and albumin (r = 0.27; p = 0.041) and ferritin (r = -0.302, p = 0.037) were determined based on our data. There were no correlations between PON-1 and hs-CRP (High sensitive C reactive protein), sedimentation, Hb, B12 and ferritin in the UC group. In the linear regression model, the leukocyte levels (p = 0.023) and Mayo UC Scores (p = 0.004) were found to have an effect on the ARE levels. In addition, it was found that in linear regression model the hs- CRP (p = 0.009) levels were found to have an effect on PON-1 levels.

Conclusion: In conclusion, ARE values that denote oxidative capacity were found to be significantly lower in patients with UC than in healthy patients. The efficacy of PON-1, an antioxidative enzyme, in UC patients is unclear. The results of our analyses suggest that there may be a correlation between ARE and PON-1 values in UC patients. Thus, it might be possible to use ARE levels as indicators of oxidative stress in UC patients. There is a need for larger studies to demonstrate the correlation between UC activity and ARE and PON-1 levels. No correlation between PON-1 and ARE levels and the activity of UC patients was detected in our study.

Introduction: Thiopurines (TPs) are commonly used in treatment of Inflammatory Bowel Disease (IBD). For Azathioprine (AZA), optimal dosing is determined by patients’ weight and commonly titrated to achieve target range of 2–2.5mg/kg. Levels of 6-thioguanine nucleotide (6-TGN), an active metabolite breakdown of thiopurines and 6-Methylmercaptopurine (6-MMP), an inactive metabolite, can be measured to check for efficacy and toxicity respectively, but this is not widely available due to cost and accessibility.

White cell count (WCC), lymphocyte count (LC) and mean corpuscular volume (MCV) have emerged as surrogate markers to monitor TP efficacy. Previous studies have suggested WCC < 4x10^9/L and MCV >100fL correlate with 6-TGN level and with reduced risk of disease relapse.

Aims and Methods: The aim of our study is to assess these surrogate parameters in our patients on TPs. 200 IBD patients being treated with AZA were included in this retrospective, observational study. Data were obtained from our IBD database and review of medical notes. Recent WCC, LC and MCV were recorded, along with body weight, AZA dose and concomitant treatment with biologic therapy (mainly anti-TNF agents).

Leucopenia was no significant difference in these measured parameters between the AZA monotherapy group, 4/117 patients (3.4%) had leucopenia and the same number of patients, 3/83 (3.4%) had macrocytosis and only 1 patient (0.9%) had both leucopenia and macrocytosis. In patients on combination therapy, 3/83 (3.6%) had leucopenia and the same number of patients, 3/83 (3.6%) had macrocytosis. None in this group had both leucopenia and macrocytosis (Table T).

Mean AZA dose to body weight in our study population was 1.7mg/kg. The mean LC was 2.86 x10^9/L (0.5 to 8.8) with mean MCV of 91.1 fl (78.4 to 104.3).

Results: There were 108 (54%) females and 92 (46%) males. Of the 200 patients, 144 (72%) were diagnosed with CD, 55 (27.5%) UC and 1 (0.5%) indeterminate colitis. Partial Mayo score for ulcerative colitis (UC) at time of blood testing. Clinical activity of UC patients was remission (n = 12, 38%), mild (n = 11, 34%), and moderate-to-severe (n = 9, 28%), respectively. UC activity was not significantly different (p = 0.120). However, UC activity was significantly correlated with MES (p = 0.031, Spearman coefficient 0.382), and clinical activity was not (p = 0.066, Spearman coefficient 0.329).

Introduction: Inflammatory bowel diseases (IBD) are chronic illness with relevant social impact. Since the great part of data are published by tertiary centers, the real burden of IBD could be not completely defined, both in terms of epidemiology and in a description of the data of a subpopulation of patients with IBD, unaware of it and asymptomatic, incidentally diagnosed in a colorectal cancer (CRC) screening program.

Aims and Methods: We have prospectively evaluated a court of people aged 50–75, undergoing screening colonoscopy after a positive faecal immunological (FIT) test, from November 2011 to March 2018. The screening program is still ongoing, and is focused to early diagnosis and prevention of colorectal cancer. Since then, 4490 patient out of 4714 FIT positive have been evaluated with colonoscopy, with a further examination of 21 patients (0.46%). A diagnosis of IBD (7 F, 14 M, mean age 64.6 years, range: 53–76), namely one Crohn’s disease (CD) and 20 ulcerative colitis (UC).

All patients are currently followed in our tertiary center, with a mean follow-up of 22 months. All UC patients are satisfactory treated with mesalazine. The only patient with CD is treated with azathioprine. Up to now, no patient had extra-intestinal manifestations, nor need for surgery.

Conclusion: There is a consistent percentage of persons with IBD that are not known as affected. There is space for improvement in diagnosis and treatment. Further studies are needed to better understand the real incidence of this condition, and the subsequent evolution of the disease in this group of patients.

Introduction: When performed, the monitoring of ADA is generally restricted to the detection of free ADA (fADA) at the trough, using drug-sensitive ADA assays. Several studies have described the detection of ADA in complex with the drug (tADA). Free ADA may underestimate the frequency of ADA-positive patients. Drug-tolerant ADA assays allow us to identify an additional proportion of ADA-positive patients. Compared to tADA+/fADA- group, patients with ADA, being more frequent in the tADA+/fADA- group when compared with tADA+/fADA+ (57% vs. 17%).

Conclusion: Drug-tolerant ADA assays allow us to identify an additional proportion of ADA+ patients. Compared to tADA+/fADA-, tADA+ patients had lower IFX levels, lower CR rates and more frequently needed switch or IFX intensification. Responses to IFX intensification were overall more favourable in this group than in the tADA+/fADA+ group. Only a minority of tADA+/ tADA+ patients became tADA+. Larger studies are warranted to confirm these results and determine the clinical benefit of including ADA assessments, to help guide therapeutic decisions, in routine clinical practice.

Disclosure: The present study has been presented as best poster oral presentation at the 16th FAPEG national meeting in Porto Alegre, Brazil.

P0309 CHROMOENDOSCOPY IS SUPERIOR TO WHITE LIGHT ENDOSCOPY FOR THE DETECTION OF ADVANCED COLONIC NEOPLASIA IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Introduction: Although recent guidelines recommend chromoendoscopy (CE) as a method of choice for neoplasia surveillance in inflammatory bowel disease (IBD), there is still controversy regarding the utility of this technique in clinical practice.

Aims and Methods: The aims of this study were to compare the accuracy of CE and white light endoscopy (WLE) for the detection of overall neoplasia and advanced neoplasia in patients with IBD. Patients who underwent surveillance colonoscopy were identified from a single institution IBD database from 1999 to 2017. Patients with prior history of colon cancer or total colectomy were excluded. CE procedures were compared with their respective WLE controls in a paired comparison and the frequency of all neoplasia, advanced neoplasia and serrated neoplasia was assessed for both targeted and random biopsies.

Results: Total 315 procedures performed in 106 individuals were identified over a median follow up 3 years (median 3 colonoscopy/patients). Among them, 290 undergoing screening colonoscopy after a positive faecal immunological (FIT) test, from November 2011 to March 2018. The screening program is still ongoing, and is focused to early diagnosis and prevention of colorectal cancer. Since then, 4490 patient out of 4714 FIT positive have been evaluated with colonoscopy, with a further examination of 21 patients (0.46%). A diagnosis of IBD (7 F, 14 M, mean age 64.6 years, range: 53–76), namely one Crohn’s disease (CD) and 20 ulcerative colitis (UC).

All patients are currently followed in our tertiary center, with a mean follow-up of 22 months. All UC patients are satisfactory treated with mesalazine. The only patient with CD is treated with azathioprine. Up to now, no patient had extra-intestinal manifestations, nor need for surgery.

Conclusion: There is a consistent percentage of persons with IBD that are not known as affected. There is space for improvement in diagnosis and treatment. Further studies are needed to better understand the real incidence of this condition, and the subsequent evolution of the disease in this group of patients.

Introduction: The combination of positron emission tomography (PET) with 18F-fluorodeoxyglucose (18F-FDG) with magnetic resonance imaging (MRI) as integrated PET/MR enterography in one examination is a new cutting-edge technology for the non-invasive assessment of the inflammatory activity in ulcerative colitis (UC). Regarding the diagnostic gold standard procedure ileocolonoscopy beside the risk of injury especially the bowel purgation is rated most bothersome.

Aims and Methods: This study’s aim was to evaluate whether the inflammatory activity in patients with UC can be detected and accurately quantified by PET/MRI with and without bowel purgation. Patients were randomized to simultaneous PET/MRI (index test) with or without bowel purgation 24h before ileocolonoscopy (reference standard). In every patient the maximum standardized uptake value ratio gut/liver (SUV Quot), an MRI index and an endoscopy index (EI; rated by 2 independent gastroenterologists) were calculated for every segment (ileum, caecum, ascending colon, transverse colon, descending colon, sigmoid colon and rectum). Sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy were calculated. Furthermore, receiver operating characteristic (ROC) curves for each colon segment were calculated to determine diagnostic accuracy of PET/MRI for the 2 modes of bowel purgation.

Results: N = 53 patients were included in the study. Ten patients were included for protocol optimization and 43 were randomized. Three patients were dropouts (two due to activity of disease other than UC, one refused examination). Therefore, 19 patients (mean age = 42.4 years (SD = 13.8 years), 11 female (57.9%), mean time since diagnosis = 13.42 years) were randomized to PET/MRI with bowel purgation and 21 patients (mean age = 43.2 years (SD = 12.7), 14 female (66.7%), mean time since diagnosis 12 years) to PET/MRI without bowel purgation. Sociodemographic and clinical characteristics did not differ between the groups. SUV Quot and EI correlated significantly for patients without bowel purgation (r = 0.46, p = 0.063). Overall sensitivity, specificity, positive predictive value, negative predictive value, and accuracy using ileocolonoscopy as reference standard are shown in table 1. ROC analyses for each bowel segment show that the diagnostic accuracy was better for patients without bowel purgation (AUC rectum = 0.87, p = 0.03; AUC sigmoid colon = 0.91, p < 0.01; AUC ascending colon = 0.86, p < 001; AUC transverse colon = 0.82, p < 0.02; AUC descending colon = 0.77, n.s.; AUC ascending colon = 0.78, n.s.; AUC transverse colon = 0.82, p = 0.02; AUC descending colon = 0.63, n.s.; AUC caecum = 0.74, n.s.) compared to patients with bowel purgation (AUC rectum = 0.69, p = 0.06; AUC sigmoid colon = 0.76, n.s.; AUC descending colon = 0.74, n.s.; AUC transverse colon = 0.82, p = 0.02; AUC descending colon = 0.63, n.s.; AUC caecum = 0.74, n.s.).

Conclusion: The inflammatory activity of UC can be detected and quantified by PET/MRI in patients who did not undergo bowel purgation prior to examination. PET/MRI might serve as a valuable complement for goldstandard ileocolonoscopy to extend the variety of non-invasive diagnostic tools in UC especially when bowel purgation is not applicable.

Introduction: Magnetic resonance imaging (MRI) with the Magnetic Resonance Index of Activity (MaRIA) and the Clermont score as validated MRI activity indices is the gold standard to diagnose and monitor small bowel Crohn’s disease (CD). However, noninvasive fecal biomarkers like calprotectin (CAL) and lactoferrin (LF) are increasingly popular and used in all-day patient care and have been evaluated regarding their capacity to differentiate and monitor disease activity in inflammatory bowel disease (IBD).

Aims and Methods: This study’s aim was to compare the performance of fecal biomarkers and MRI for monitoring inflammatory activity in patients with CD. Fecal samples were collected to determine LF, CAL, PMN-elastasis (PMN-e), S100 calcium-binding protein A12 (S100A12), and Eosinophil-derived Neurotixin (EDN) by enzyme immunoassay (EIA). In every patient a MRI was performed, MaRIA and the Clermont score were calculated, and standard cut-offs were applied by two independent experienced radiologists. Receiver operating characteristic (ROC) curves for each fecal biomarker using MaRIA and Clermont score as reference standard were calculated to determine sensitivity, specificity, and accuracy using optimized cut-offs.

Results: N = 50 patients with CD (mean age = 43.1 years (SD = 13.42), 32 female (64%), mean time since diagnosis = 13.8 years) were included in the study. According the MaRIA score n = 41 patients and according to the Clermont score n = 40 patients showed signs of active inflammation. Mean levels for patients with active/inactive inflammation were 12.43/1.90(µg/g) in LF, 22.84/6 151.17(µg/g) in EDN, 17.0.09(µg/g) in PMN-e, 64.91/79.99(µg/g) in S100A12 and 4.0.47(µg/g) in EDN. Fecal LF, CAL and EDN were significantly

Introduction: Patients with inflammatory bowel disease (IBD) are at high risk of colorectal cancer (CRC). Today American and European guidelines recommend surveillance with endoscopy rather than colonoscopy after complete resection of endoscopically resectable dysplastic lesions using chromoendoscopy. 1,2 However very few prospective data exist to evaluate the application of these recommendations and patient outcome. Moreover, the endoscopic techniques that should be used for lesion excision is not well defined.

Aims and Methods: Describe within a multi-centre prospective cohort the management and follow-up of dysplasia in IBD patients.

Results: In November 2017, 60 patients were included among 14 centers. 43 patients had UC (71.7%), and 17 patients had CD (28.3%). The median follow-up time from the first diagnosis of dysplasia was of 10 years. The median follow-up time with prospective evaluation was of 9.9 years. 25 patients were initially diagnosed with an adenomatous lesion with low-grade dysplasia (LGD; 86.7%), 6 with an adenomatous lesion with high-grade dysplasia (HGD; 0.1%) and 1 CD patient had a serrated poly with low-grade dysplasia.

Conclusion: From September 2013 to November 2017, 60 patients were included procedure and histological results were assessed all along the study.

Introduction: To assess the relevance of including perianal region in routine CT/ MR enterography for detection of perianal dysplasia in Crohn’s disease (CD), according to recent consensus recommendations.

Aims and Methods: Identification of patients undergoing enterography. Selection of examinations performed with perianal extension in patients with CD.

Results: A retrospective classification with identification of perianal disease. Evaluation of enterographies for signs of perianal disease, blinded to Montreal classification. Statistics: Kappa concordance test (p ≤ 0.05). Radiation increase estimation due to perianal extension, in a Siemens Somaton® 16 CT equipment with filtered back projection (FBP) reconstruction.

Conclusion: The extension of enterography to the perianal region has not shown to be superior to clinical evaluation for detection of perianal disease in CD. The consensus rather than colorectal MR enterography may be prudent only for MR enterography, since CT enterography incurs a non-negligible added radiation and exposure of radiosensitive organs, that otherwise would not be covered.

Contact E-Mail Address: gallagach6@tcd.ie

Introduction: Inflammatory Bowel Disease (IBD) patients are at risk of Malignant Melanoma (MM) and non-melanoma skin cancer (NMSC). Simple photo protective measures and early detection through increased vigilance can reduce the incidence and the burden of disease. Traditional educational methods have had limited impact and newer validated educational tools are needed.

Aims and Methods: To assess the impact and validate a novel IBD educational video animation on skin cancer awareness in a cohort of Irish IBD subjects.

Results: A prospective non-randomised interventional study using our novel, recently trialled IBD tailored educational animation video based on the Irish Cancer Society ‘Sunsmart Guidelines’. Self assessment questionnaires were employed to collect patient demographics and assess sun smart behaviours. The test was at 2 sequential IBD clinics, one where the video was played in the outpatient waiting area (exposed group) and another without any video (control group). The questionnaire included sections on what factor sunseeker to wear and how often to re-apply it, when to stay in the shade, and how to perform a self skin check including what suspicious changes to look for in a suspicious mole. Results were compared among groups using a Chi Squared test (p ≤ 0.05 was considered significant) and an odds ratio (OR) calculated where appropriate.
PO315 IBD PATIENTS ARE FOUR TIMES MORE LIKELY TO DEVELOP ALL TYPES OF SKIN CANCER POSSIBLY RELATED TO HIGH RATES OF IMMunosUPPRESSION; WITH YOUNG IBD PATIENTS PARTICULARLY AT RISK OF SKIN CANCER

Introduction: Increased rates of non-melanoma skin cancer (NMSC) is a recognised complication of immunosuppression therapy for inflammatory bowel disease (IBD), while little is known of malignant melanoma (MM) risk. New therapies, including biologics, their early age of introduction and longer duration may increase skin cancer risk.

Aims and Methods: To compare the incidence of both NMSC and MM in an Irish IBD cohort compared to controls. Retrospective single centre case-control study from 2012-2017. Known IBD patients and age and sex matched controls were identified from an IBD and polyp database respectively. Both cohorts were cross-referenced with our hospital’s pathology database for NMSC and MM. Patients otherwise at risk of skin cancer including transplant recipients or other indications for long-term immunosuppression and skin cancer genetic syndromes were excluded following review of patient electronic records.

The rates of NMSC and MM were compared among groups using a Chi-squared test (p < 0.05 was considered significant), and the impact of age, gender and immunosuppression use was evaluated using a logistic regression model. Rates of NMSC and MM were compared during groups using a Chi-squared test (p < 0.05 was considered significant), and the impact of age, gender and immunosuppression use was evaluated using a logistic regression model. Rates of NMSC and MM were compared during groups using a Chi-squared test (p < 0.05 was considered significant), and the impact of age, gender and immunosuppression use was evaluated using a logistic regression model.

Results: In all, 931 IBD and 1090 age and sex matched controls were identified. In all, 931 IBD and 1090 age and sex matched controls were identified. In all, 931 IBD and 1090 age and sex matched controls were identified. In all, 931 IBD and 1090 age and sex matched controls were identified. In all, 931 IBD and 1090 age and sex matched controls were identified. In all, 931 IBD and 1090 age and sex matched controls were identified. In all, 931 IBD and 1090 age and sex matched controls were identified. In all, 931 IBD and 1090 age and sex matched controls were identified.

Conclusion: Serum hepcidin is a very important novel marker in patients with iron deficiency anemia (IDA), and it should be used in IBD patients considering difficulties in establishing IDA diagnosis due to inflammation.

Contact E-Mail Address: drmilicastojkovic@gmail.com

Introduction: Iron metabolism is regulated by hepcidin, polypeptide synthesized primarily by hepatocytes. Hepcidin synthesis may be altered due to hypoxia, inflammation, erythropoiesis and other multiple factors that have an influence on total iron body storage.

Aims and Methods: Our aim was to determine serum hepcidin levels in patients inflammatory bowel disease (IBD) as well to investigate whether there is correlation of hepcidin levels with disease activity.

In a retrospective study was performed on 30 newly diagnosed IBD patients (18 UC, 12 CD) and the same number age, sex-matched healthy controls. All patients underwent a total colonoscopy with ileoscopy. Complete blood count was obtained in addition to inflammatory markers (CRP, erythocyte sedimentation rate) and serum levels of hepcidin were determined with commercially available enzyme-linked immunosorbent assay (DRG Instruments, Marburg, Germany). Serum iron, TIBC, UIBC were assessed with an electrochemiluminescence immunomessay and sTfR was assessed using an immunoturbidimetric method. Mayo score and CDAI respectively were calculated respectively for IBD and control patients. Statistical analyses were performed using SPSS software version 20.0 for Windows.

Results: There was high statistically significant difference between IBD patients and controls in levels of hepcidin (p < 0.01). Serum hepcidin levels were significantly higher in control group (9.77 ± 2.71 vs. 6.40 ± 2.42 ng/ml, p = 0.000). Serum ferritin (394 ± 5.15 vs. 119 ± 124 ng/ml, p = 0.000) as well as serum ferritin ratios were significantly higher in control group. There was no statistically significant correlation of serum hepcidin with CRP, Mayo score or CDAI respectively (p > 0.05). However we have found statistically significant negative correlation of sTfR, TIBC with hepcidin (p < 0.01). Combined Serum hepcidin is a very important novel marker in patients with iron deficiency anemia (IDA), and it should be used in IBD patients considering difficulties in establishing IDA diagnosis due to inflammation.

Disclosure: Nothing to disclose

PO317 MONITORING HISTOLoGICAL ACTIVITY IN ULCERATIVE COLITIS - CORRELATION OF FECal BIOMARKERS WITH THE RILEY SCORE AND THE NANCY INDEX

J Langhorst1,2, D Schroeder1,2, A Koch1,2, GJ Dobos3, H Boone1, A Rueffer2, H Jutel1, A Tannapfel1

2University of Duisburg-Essen, Klinikum Essen-Mitte, Department for Internal and Integrative Medicine, Essen, Germany
3TechLab, Research and Development, Blackburg, United States

Contact E-Mail Address: j.langhorst@klinikum-essen-mitte.de

Introduction: Histological healing in ulcerative colitis (UC) may be a better predictor than macroscopic appearance or clinical criteria for time to relapse. Histological assessment revealed that indicators of acute mucosal inflammation, including crypt abscesses, mucin depletion or an acute inflammatory cell infiltrate which are used in the Riley Score or the Nancy index were associated with a 2- to 3-fold increase in the risk of UC relapse during 12 months’ follow-up. Histological assessment that requires invasive endoscopy and gaining of biopsy. Non-invasive surrogates of mucosal healing like fecal biomarkers would help to lower risks, costs and might increase patient acceptance.

Aims and Methods: The study aimed to investigate the performance of non-invasive fecal biomarkers compared to the Riley Score and the Nancy index in patients with UC. Colonooscopy was performed in every patient and a fecal sample was collected during 72 hours. Three biopsies were taken from the macroscopically most inflamed region or random biopsies of the colonic segment and the Riley Score and Nancy index were calculated. For each patient the highest calculated score was compared to the fecal biomarkers lactoferrin (LF), calprotectin (CALPREST - CalPi), PMN elastase (PMN-E), S100 calcium-binding protein A12 (S100A12) and Esinophil-derived Neurotoxin (EDN). In addition, a Kruskal-Wallis test was performed to evaluate if the median levels of the fecal markers differ significantly between the grades 0-4 of the Nancy index.

Results: 50 patients (32 female), mean age 42.9 ± 12.3 years (range 23-67) with diagnosed UC were included in the study. The Riley Score and the Nancy index were correlated significantly with EDN (r (49) = 0.561; p = 0.001) and LF (r (49) = 0.455; p = 0.000), S100A12 (r (49) = 0.327; p = 0.022) and S100A12 (r (49) = 0.346; p = 0.015), PMN-e (r (49) = 0.314; p = 0.028) and LF (r (49) = 0.452; p = 0.001), S100A12 (r (49) = 0.345; p = 0.015), but not with CalPi (p > 0.05). The median levels of the fecal markers correlating with the grades 0-4 of the Nancy index and the results of the Kruskal-Wallis test is presented in table 1. Only LF, EDN and S100A12 differed significantly between the grades. Subsequent post-hoc tests showed that LF differed significantly between the grades 2 and 3 (z = -3.125, p = 0.001), EDN between the grades 2 and 4 (z = -3.006, p = 0.016) and S100A12 between the grades 2 and 3 (z = -3.986, p = 0.000) and 2 and 4 (z = -3.067, p = 0.013).

Conclusion: The fecal biomarkers LF, EDN, S100A12 and PMN-e were correlated significantly with the Riley and Nancy index, LF, EDN and S100A12 differed significantly between the grades of the Nancy index. The results support the utility of fecal biomarkers for detecting active histologic inflammation in patients with ulcerative colitis.

P0318 AZATHIOPRINE METABOLITE (6-TGN) LEVELS WITHIN A DEFINED THERAPEUTIC RANGE ARE ASSOCIATED WITH LOWER FECAL CALPROTECTIN IN CROHN’S DISEASE - A RETROSPECTIVE ANALYSIS

J Eismann1, C Keil1, O Unruh2, A Oete2, M Manns1, O Bachmann1
1Hannover Medical School, Dept. of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany
2University Medical Center Göttingen, Institute for Clinical Chemistry, Göttingen, Germany

Contact E-Mail Address: bachmann.oliver@mh-hannover.de

Introduction: Azathioprine/6-mercaptopurine (AZA/6-MP) are first-line immunosuppressants for the treatment of Crohn’s disease. While recent meta-analyses have reported a positive association of their active metabolite 6-thioguanine (6-TGN) with clinical outcomes, 6-TGN levels have not been correlated with surrogate markers of mucosal healing, which is an increasingly recognised therapeutic goal.

Aims and Methods: We therefore investigated whether 6-TGN levels are inversely associated with fecal calprotectin (FC) in Crohn’s disease patients on azathioprine monotherapy. 6-TGN and FC levels of 96 Crohn’s disease patients on AZA/6-MP monotherapy visiting the IBD outpatient clinic between 2009 and 2016 were retrospectively analysed. In a small sub-cohort with serial 6-TGN measurements, longitudinal FC measurements were assessed.

Results: In patients with 6-TGN levels within a defined range (250-450 pmol/8 x 10^9 RBCs), FC levels were significantly lower (median FC 149 vs. 346 mg/kg, p = 0.007), and hemoglobin concentrations as well as transferrin saturation levels were significantly higher than in patients with lower or higher metabolites. CRP and protein levels were not different. In the small cohort that was followed longitudinally, all patients achieved an increase in 6-TGN levels upon dose escalation, and fecal calprotectin levels decreased in 54%.

Conclusion: In our retrospective analysis on Crohn’s disease patients receiving AZA/6-MP monotherapy, 6-TGN levels within a defined range (250-450 pmol/8 x 10^9 red blood cells) were associated with significantly lower fecal calprotectin levels. A treat-to-target concept directed by 6-TGN levels to reach mucosal healing appears promising, but requires prospective studies (DRKS00013246).

P0319 DEVELOPMENT AND VALIDATION OF A SIMPLIFIED MAGNETIC RESONANCE INDEX OF ACTIVITY (SMARIA) FOR CROHN’S DISEASE

1Hospital Clinic of Barcelona, Gastroenterology, Barcelona, Spain
2Hospital de Clinic Barcelona, Radiology, Barcelona, Spain
3Hospital Clinic of Barcelona, Gastroenterology, Barcelona, Spain

Contact E-Mail Address: iordas@clinic.ub.es

Introduction: The MaRIA index is the best-characterized Magnetic Resonance Enterography (MRE) index for the assessment of luminal Crohn’s disease (CD) activity. However, a number of limitations had been recognized.

Aims and Methods: The aim of this study was to develop and to validate a simplified and accurate Magnetic Resonance Index of Activity (sMaRIA) for assessing disease activity and therapeutic response of luminal CD. MRE data from 98 patients, including active and inactive segments (colon and terminal ileum), from 2 prospective studies were re-analyzed to develop the sMaRIA using endoscopy (CDEIS) as gold standard. Further analysis of responsiveness and reliability, in an independent cohort of 37 patients who underwent MRE and endoscopy before and after a therapeutic intervention was performed. Comparison of the diagnostic performance between the original MaRIA and sMaRIA for detecting active/severe lesions was performed.

Results: Logistic regression analysis showed that wall thickness > 3 mm, presence of mural edema, ulcers and perienteric fat stranding were independent predictors of disease activity and were used therefore as descriptors of sMaRIA. The sensitivity and specificity of sMaRIA at segment level for detecting active disease using a cutoff point ≥1 were 90% and 81% (AUC 0.91, 95% CI 0.88-0.94), and for detecting severe lesions (ulcers) using a cutoff point ≥2 were 85% and 92% (AUC 0.94, 95% CI 0.91-0.96), respectively. Correlation between sMaRIA and CDEIS/MaRIA was excellent (r = 0.82 and r = 0.91, respectively; p < 0.001). There were no differences with regard to diagnostic performance between the sMaRIA and the original MaRIA for detecting active (p = 0.7) and severe disease (p = 0.5). The sMaRIA accurately detected changes in lesion severity in response to a therapeutic intervention and was as reliable as endoscopy for the assessment of mucosal healing.

Conclusion: Simplified MaRIA index allows a faster and easier assessment of inflammation in CD by keeping high accuracy for both diagnosis and therapeutic response. Main advantages over MaRIA include a less time-consuming calculation and that it is not confounded by missing segments.

Introduction: The ulcerative colitis endoscopic index of severity (UCEIS) is a novel, validated instrument to evaluate endoscopic disease activity in ulcerative colitis (UC). Recent studies have demonstrated that the UCEIS outperforms the more widely used Mayo endoscopic score (MES) in predicting long-term prognosis (2,3), including the need for colectomy (4). It also has precise item definitions and is likely to be more responsive than the MES score by virtue of its greater number of stratifications (scores range between 0-8, as opposed to 0-3). However, despite these potential benefits many gastroenterologists still prefer to use MES, because its operating characteristics are better defined and its grades are more readily applicable to clinical decision making: a MES ≥ 2 is generally accepted as the cut-off for treatment escalation (5). The equivalent for the UCEIS cut-off is not yet defined, which limits its clinical utility.

Aims and Methods: Our aims were to determine a UCEIS threshold most closely associated with the need for treatment escalation as well as to perform a validation exercise using clinical, biochemical and histological measures of disease activity. Colonoscopies and sigmoidoscopies performed in UC patients between Nov 2016-Jan 2018 at Guy’s and St Thomas’ Hospital were retrospectively reviewed. Detailed demographic, UC phenotype and medication, Simple Clinical Colitis Activity Index (SCCAI), UCEIS, MES, CRP and Nancy Histological Index (NHI) were collected as well as treatment alteration decisions based on endoscopic findings.

The measure of agreement between the UCEIS and the Mayo score was examined using Kappa (κ) statistics. A UCEIS cut-off for the perceived need for treatment escalation was calculated using a Chi square test, receiver operating characteristic (ROC) curve and area under the curve (AUC) analyses. Pearson correlation coefficient was used to compare the linear relationship between the UCEIS and SCCAI, CRP and NHI.

Results: 363 endoscopic procedures were carried out in 295 patients during the data collection period. 201 of the 363 procedures (56%) documented both the UCEIS and MES. These scores demonstrated a substantial agreement between the indices (κ = 0.713, p < 0.001).

Overall, treatment escalation was considered necessary following 199 (56%) procedures, but was not in the remaining 156 (44%). ROC analysis of the perceived need for treatment escalation showed the highest sensitivity and specificity (0.80 and 0.93, respectively) for UCEIS ≥ 4 with an AUC of 0.93. Of 170 patients with a UCEIS ≥ 4, treatment escalation was considered necessary for 159 (94%), but not for 11 (6%). Of 185 patients with a UCEIS ≥ 3, treatment escalation was considered necessary in 40 (22%), cases but was not in 145 (78%) cases (p < 0.001).

UCEIS values demonstrated moderate correlation with SCCAI (0.671, p < 0.001) scores and strong correlation with NHI values (0.723, p < 0.001), but only weak correlation with CRP measurements (0.279, p < 0.001).

Conclusion: Our data demonstrate that a UCEIS score ≥ 4 was significantly associated with the perceived need for treatment escalation. This cut-off could/should therefore be used to support clinical decision-making based on endoscopic findings. Our results also showed that UCEIS has strong correlation with histological disease activity, moderate correlation with a clinical activity index, but only weak correlation with CRP.

P0232 - EVALUATION OF CROHN'S DISEASE BY USING A NOVEL CAPSULE ENDOSCOPY SCORING METHOD: CROHN'S DISEASE ACTIVITY IN CAPSULE ENDOSCOPY (CDACE)

Tokyo Women's Medical University, Institute of Gastroenterology, Tokyo, Japan

Contact E-Mail Address: tohomi@ige.twmu.ac.jp

Introduction: Small bowel capsule endoscopy (SBCE) for Crohn's disease (CD) with small bowel lesions is a low-invasive method that enables visualization of the small bowel mucosa. Two scoring methods are used to evaluate the images obtained: the Lewis score (LS) and the capsule endoscopy Crohn's disease activity index (CDACE). However, CDACE shows varied pathology, including inflammation and stenosis; it is difficult to assess the disease state, including the range of lesions, and presence/absence of stenosis solely on the basis of the sum scores obtained by either one of the scoring methods.

Aims and Methods: To develop and evaluate a novel scoring method with which pathology can readily be assessed from sum scores by using SBCE data of CD patients with small bowel lesions. The subjects included 93 CD patients with small bowel lesions who underwent SBCE between June 2010 and May 2017. SBCE was carried out a total of 162 times in these patients, including 104 times in men, 49 times for small bowel CD, and 113 times for small-and-large bowel CD. The novel scoring method was established as Crohn's disease activity in capsule endoscopy (CDACE), and its correlations with the scoring methods in current use, LS and CECDAI, and also with the clinical disease activity index (CDAI) and biomarkers, were analyzed. In CDACE, the small bowel was divided into four zones according to Rapid software analysis, and for each zone, the inflammation score was scored on a scale of 0 to 4, giving a total score of 0 to 16 (inflammation present), inflammation score was scored on a scale of 0 to 4 (score of CDAI: C). CDACE was calculated as the sum of A x 100 + B x 10 + C.

Results: The correlations between CDACE and the existing scoring methods were as follows: CDACE and the LS: r = 0.44 (p < 0.0001) and CDACE and the CECDAI: r = 0.83 (p < 0.0001). Thus, the correlation with the CECDAI was high. Therefore, CDACE, the LS and CECDAI, showed a high degree of correlation between each of the CDAI and biomarkers were as follows: CDAI: r = 0.39 (p < 0.0001), r = 0.19 (p = 0.0119), and r = 0.37 (p < 0.0001) and C-reactive protein (CRP): r = 0.23 (p = 0.0027), r = 0.05 (p = 0.5201), and r = 0.24 (p = 0.0018). Therefore, CDACE and the CECDAI showed approximately the same correlations with the CDAI and CRP.

Conclusion: With CDACE, it is possible to interpret the inflammation morphology (the second third fourth digit) and the severity and presence/absence of stenosis (the first digit) in the small bowel on the basis of the sum scores obtained. In addition, the correlation with the CECDAI has been clearly demonstrated. Therefore, CDACE represents a novel, useful scoring method in clinical practice for patients who underwent SBCE for CD with small bowel lesions.

P0234 - LONG-TERM OBSERVATION REGISTRY -CEDUR - IN GERMAN IBD PATIENTS

S. Howard1, T. Ochsenknechtm1
1HeiferCure, Kolding, Denmark
2Inflammatory Bowel Disease, Munic, Germany

Contact E-Mail Address: thoward@heifercure.de

Introduction: Inflammatory bowel disease (IBD) is diagnosed in approximately 35000 patients in Germany with increasing incidence and prevalence. Although on-going inflammation can result in irreversible damage to the GI tract, under-treatment and reluctance to use immunomodulatory therapies earlier in the course of disease are present. On the other hand, costs for therapies, surgeries and hospitalization are high, once damage has occurred. In 2015 we therefore implemented an independent national IBD registry (CEDUR) to methodically collect real-life data of IBD patients with regard to the usefulness and comparability of immunomodulatory strategies.

Aims and Methodic CEDUR is a web-based, descriptive registry of large tertiary IBD centers throughout Germany, using time sparing documentation in an adapted medical charts-software via GDT interface. Patients with IBD who are willing to participate have visits every 3 months at their clinic and are later-on completed and controlled by their physicians. Since 2015 and for at least 10 years, data on phenotypes, therapeutic effects including efficacy, safety and economy as well as as hospitalizations, surgeries, comorbidities, day-off work, costs for therapies, hospitalization are high, once damage has occurred. In 2015 we therefore implemented an independent national IBD registry (CEDUR) to methodically collect real-life data of IBD patients with regard to the usefulness and comparability of immunomodulatory strategies.

Introduction: Patients with ulcerative colitis (UC) experience periods of recurring and episodic clinical signs and symptoms. This study sought to establish the association between disease activity and health-related quality of life and other patient-reported outcomes.

Aims and Methods: Data from the 2015 and 2017 Adelphi Inflammatory Bowel Disease Specific Programmes (IBD-DSP) were used. The IBD-DSP is a database of patient chart information abstracted by selected gastroenterologists across the European Union Five [EU5]: i.e., Germany, Italy, Spain, and the United Kingdom [UK]. Eligible gastroenterologists who agreed to participate were asked to complete patient record forms for their next 7 consecutive eligible adult patients with UC. Using available chart information (including endoscopy results based on Mayo scoring), physicians classified their patients into 1 of the following categories: remission with an endoscopic score of ≤1, minimal disease (MD), and moderate to severe disease (M-TSD). Those who had used either an immunomodulator [IM] or a biologic were excluded. Differences among disease activity categories with respect to patient-reported outcomes were analyzed using generalized linear models, controlling for demographic (age, sex, and country) and clinical factors (body mass index, smoking history, years diagnosed, and a Charlson comorbidity index) as confounders.

Results: A total of N = 1037 patient charts with linked surveys were included (France: N = 347; Germany: N = 379; Italy: N = 55; Spain: N = 171; UK: N = 85; 55.6% male, mean age = 39.2 SD = 13.8). Patients had been diagnosed for a mean of 5.3 years (SD = 5.9). 33.6% had active disease, 53.0% were in remission, and 13.3% were in deep remission. Patients with active disease reported significantly lower levels of EQ-5D health state utilities (Adjusted Mean (AdjM) = 0.78) compared with remission (AdjM = 0.91) and deep remission (AdjM = 0.91) (both p < 0.05).

Conclusion: Among patients with moderate-to-severe UC in EU5, active disease was associated with significant impairments in health-related quality of life and impairments in work and leisure activities.

Contact E-Mail Address: qjguo@abbbvie.com

Introduction: Crohn’s Disease (CD) features segmental inflammation, which can affect any part of the gastrointestinal tract, with lesions extending across all tissue layers. Although endoscopy and histology can be used to monitor mucosal disease, in vivo assessment of progression and regression of transmural lesions, especially in the small bowel remains challenging. The 18 kDa translocator protein (TSPO), located on the mitochondrial outer membrane, is overexpressed in activated macrophages, and has been used as a marker of inflammation. PET imaging with TSPO selective radioligands allows for the noninvasive assessment of Crohn’s Disease inflammation, and has been used extensively in both brain and peripheral inflammatory diseases.

Aims and Methods: Here we aim to evaluate the utility of TSPO PET, using radioligand [11C]PBR28, for assessing the inflammation in the gastrointestinal tract in subjects with CD compared to healthy subjects. Subjects were recruited by Hammersmith Medicines Research. For subjects with CD, inclusion criteria included CD confirmed by endoscopy, and then being naïve to biologics. 4 CD patients (2 males and 2 females) and 5 healthy volunteers (3 males and 2 females) have been recruited to date and undergone 2 dynamic [11C]PBR28 PET-CT scans; baseline and 2 hours post a 90 mg oral dose of XB173 on the same day. XB173 is a TSPO selective compound and is thereby used to confirm the specificity of the signal in this particular application. Patient Crohn’s Disease Activity Index (CDAI), C-reactive protein (CRP), Faecal Calprotectin (FC) as well as TSPO m6971 genotype (a common polymorphism in the TSPO gene which affects ligand binding properties) were measured at screening. Regions of interest (ROIs) were manually delineated on the terminal ileum, small bowel, descending colon, sigmoid colon, and skeletal muscle in each subject based on PET and CT co-registered images. The mean and max standard uptake values (SUVs, radioactivity concentration normalized by total injected activity and body weight) were estimated in these ROIs.

Results: The CDAI of the CD patients ranges from 116 to 172, with CRP ranges from 0.2 to 3.8 mg/L, and FC from 49 to 510 mg/kg. Among the 4 CD patients, 3 are high affinity binders (HABs) and 1 is a mixed affinity binder (MAB). There are 2 HABs and 3 MABs in the control group. Compared to healthy controls, CD patients showed a trend of higher heterogeneous ligand uptake in the GI tract, especially in the small bowel. The mean SUVs in different ROIs are listed in the table below.

Conclusion: Preliminary data suggest that the observed PET signal in the small bowel of CD patients can be attributed to TSPO, and by inference inflammatory activity. Should these results to be confirmed, TSPO PET may allow the identification of inflammatory foci in the GI tract of Crohn’s patients even with mild disease activities, providing a non-invasive method to assess and quantify inflammatory activity not captured by endoscopy. Recruitment into this pilot study continues.

Disclosure: Qi Guo, Just Genius, Yanping Luo, and Robert Comley are employees of AbbVie. Gaia Rizzo, Eugenii Rabiner and Azeem Saleem are employees of Invicro. Masli Walther and Matilde Luce are employees of Hammersmith Medicines Research.

P0331 DEPENDENCE OF THE LEVEL OF INFLAMMATION MARKERS ON THE PRESENCE OF CLOSTRIDIAL INFECTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

O Knyazev, A Karamanova, A Lishchinskaya, I Korneeva, A Parfenov

Moscow Clinical Scientific Center named after A.S. Logvinov, Inflammatory Bowel Diseases, Moscow, Russian Federation

Contact E-Mail Address: karamanova@me.com

Introduction: In patients with inflammatory bowel disease (IBD), there was a more frequent development of clostridial infection (CI) and much higher morbidity and mortality rates compared with patients without IBD. Immunosuppressive therapy is a risk factor.

Aims and Methods: We aimed to determine the frequency of clostridial infection (CI) in patients with inflammatory bowel disease undergoing treatment in the Department of treatment of IBD Moscow Clinical Research Center. Of the 1224 patients with IBD, 764 were found to have toxins A and B in feces by enzyme immunoassay. Comparative analysis...
between the groups was performed by the method of 4-field tables using non-parametric testing.

**Results:** CI was found in 132 (17.3%) patients of IBD, patients without CI - 632 (82.7%). Among IBD patients with CI men - 61 (46.2%), without CI men - 313 (49.5%). Extraintestinal manifestations were present in 31 (28%) patients with IBD with CI, in 174 (27.5%) - without CI (p = 0.05). The mean albumin level in patients with CI was 28.4±2.8 g/l, in the group without CI - 35.6±3.7 g/l (p = 0.012836). The mean level of CRP among patients with CI was 65.9±4.8 mg/l, in the group without CI - 37.8±3.7 mg/l (p = 0.000004). The mean level of ESR was 45.5±6.5 mm/h, in the group without CI - 19.4±3.3 mm/h (p = 0.000991). The mean level of fecal calprotectin among patients with CI was 1680±120 mg/g, in the group without CI - 480±195 mg/g (p = 0.00000).

**Conclusion:** The activity of the inflammatory process is higher in patients with inflammation associated with associated clostridial infection.

**Disclosure:** Nothing to disclose.

**P3032 MICROBIOTA PROFILE AND DYSBIOSIS ASSESSMENT IN CLINICAL PRACTICE: A PILOT STUDY ON IBD PATIENTS**

**Introduction:** A growing body of evidence suggests that dysbiosis plays a key role in the pathogenesis of inflammatory bowel disease (IBD). However, due to intrinsic limitations in current diagnostic methods and lack of agreement on the appropriate test to use, in clinical practice the characterization of dysbiosis in IBD patients remains challenging.

**Aims and Methods:** We compared a commercially available dysbiosis test and a stool standard analysis test to profile the microbiota at phylum level in IBD patients and healthy control subjects. Human fecal samples from 13 IBD patients and 4 healthy control subjects were examined by the GA-map™ Dysbiosis Test (Oslo, Norway) and Illumina MiSeq test by BMR-genomics (Padova, Italy). GA-Map is a 16S rRNA test that utilize 54 DNA probes based on 7 variable regions (V3-V9) and recognizing gut bacteria profiles for identification and characterization of dysbiosis. The BMR-genomic test applies the universal primer based on the V3-V4 hypervariable region of 16S rRNA using an Illumina MiSeq next-generation sequencer. The correlation between variation of microbiota expressed as the Dysbiosis Index region of 16S rRNA using an Illumina MiSeq next-generation sequencer. The BMR-genomic test applies the universal primer based on the V3-V4 hypervariable region of 16S rRNA using an Illumina MiSeq next-generation sequencer. The correlation between variation of microbiota expressed as the Dysbiosis Index (DI) and fecal calprotectin (FC) levels in IBD patients was also investigated.

**Results:** BMR-GENOMICS reports on the relative abundance (%) of the major phyla on IBDs microbiota. So far, we compared the trend of BMR-genomics reports on the relative abundance (%) of the major phyla with normalized signal

**Introduction:** Golimumab is approved as a therapy for ulcerative colitis (UC) patients. Recently data also demonstrated efficacy and mucosal healing in Crohn’s disease (CD); however, little is known regarding target drug levels. Our aim is to identify trough golimumab levels in IBD associated with endoscopic remission.

**Aims and Methods:** This was a retrospective analysis of patients on maintenance golimumab for a minimum of 4 months. Concomitant therapies, disease status at the time of levels, endoscopic and clinical response (significant reduction in symptoms and biochemical markers with weaning of steroids) were recorded. Endoscopic and radiology records approximate to the date of the assay were reviewed. Primary outcome was mucosal healing defined as Mayo 0-1 or SES-CD score < 5. Secondary outcomes included clinical remission and endoscopic improvement. Drug levels were measured with Dynasure assay, mean trough levels compared using Kruskal-Wallis test, and used logistic regression to construct a probabilistic model determining sensitivity and specificity of levels predicting mucosal healing.

**References:**
1. Varela N, Yáñez-Barquín P, Lilley BN, Liu Y, Liu D, Mokler S, Gleichmann C, Zeligman J, Liu X, Maloney L, et al. Quantitation of adalimumab within the clinically relevant 0.5–25 µg/mL concentration range. The RIDA®QUICK ADM Monitoring allows accurate and precise quantification of adalimumab within the clinically relevant 0.5–25 µg/mL concentration range. The RIDA®QUICK ADM Monitoring shows excellent agreement with the RIDASCREEN® ADM Monitoring, which uses the same highly specific antibody clone to adalimumab. The RIDA®QUICK ADM Monitoring is easily accessible and supports timely dose adjustments of patients receiving adalimumab treatment in routine clinical practice.

**Disclosure:** Chris Barthel, Karin Wagenhäuser, Daniela Fichtner, Steffen Rameil, Thomas Van Stappen are employees of R-Biopharm AG (Darmstadt, Germany).
mean level was higher in patients with mucosal healing (n = 8, mean 5.9 μg/mL) vs non-response (n = 5, mean 2 μg/mL, p = 0.06) although analysis was limited by lower numbers in this cohort.

Conclusion: Treatment with golimumab was associated with mucosal healing in 45% IBD patients. Higher golimumab levels were associated with mucosal healing in CD and trough levels > 6.1 μg/mL were associated with endoscopic remission.

Introduction: The efficacy and safety of adalimumab induction and maintenance treatment in Chinese patients with moderately and severely active Crohn’s disease (CD) were assessed in a 26-week, phase 3, randomized, double-blind, placebo-controlled, multicenter study.

Aims and Methods: Adult patients naïve to anti-TNF therapy (CD Activity Index [CDAI] 220–450, hs-CRP≤3 mg/L) were stratified by CDAI (>300 ≥300) and corticosteroid use (yes/no) at baseline and randomized (1:1) to double-blind adalimumab 160 mg at weeks 0, 2, 40 mg at weeks 4/6 or placebo at weeks 0/2 followed by blinded adalimumab 160/80 mg at weeks 4/6. At week 8, all patients received open label (OL) 40 mg adalimumab every other week for up to 18 weeks. The primary endpoint (clinical remission [CDAI < 150]) and key secondary endpoints (Table) were assessed at week 4 between adalimumab and placebo using the Cochrane-Mantel-Haenszel (CMH) test and stratified by the randomization factors. Clinical remission at week 26 was assessed in patients with response (decrease CDAI ≥70 points from baseline) at week 8 and compared with a clinically meaningful threshold of 30% using the 1 sample Exact test.

Adverse events (AE) were collected throughout the study.

Results: Of 205 randomized patients (65 [31.7%] female, 32.9 [9.9] mean [SD] years of age and 2.7 [3.0] years disease duration), 196 (95.6%) completed the induction period and 159 (77.6%) completed OL treatment to week 26. The primary endpoint and key secondary endpoints were met (Table). Serious AEs and serious infections, respectively, were reported in 2/102 (2.0%) and 0 patients with adalimumab, 1/103 (1.0%) and 0 patients with placebo during double-blind treatment and in 36/200 (18.0%) and 7/200 (3.5%) patients receiving any adalimumab during the trial.

Conclusion: Adalimumab induced and maintained clinical remission and response in Chinese patients with CD who failed conventional therapy. The safety profile of adalimumab was generally comparable with placebo and consistent with the known safety profile of adalimumab.

Introduction: Upadacitinib (UPA) is an oral, selective Janus kinase 1 inhibitor that is being assessed in patients with ulcerative colitis (UC). The effects of UPA on patient-reported outcomes (PRO) were evaluated in the double-blind placebo-controlled dose-ranging 8-week induction portion of the phase 2b/3 study (U-ACHIEVE [NCT02819635]).

Aims and Methods: Adult patients with moderately to severely active UC (Adapted Mayo score [Mayo score without Physician Global Assessment] 5–9 points and centrally-read endoscopy subscore 2–3) who had inadequate response or intolerance to immunosuppressants, corticosteroids, or biologics were randomly assigned in a 1:1:1:1 ratio to double-blind induction therapy with placebo (PBO) or the modified-release formulation of UPA at 7.5, 15, 30, or 45 mg once daily (QD) for 8 weeks. Patients answered the following PRO questionnaires at baseline, and Week 2, 4, and 8: Inflammatory Bowel Disease Questionnaire (IBDQ), EuroQol–5 dimensions (EQ-5D), 36-Item Short Form Health Survey (SF-36), Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F), and Work Productivity and Activity Impairment (WPAI).

Mean change from baseline to Week 2 was assessed using analysis of covariance; missing data were reported using last observation carried forward. The percentage of patients with IBDQ response, defined as increase ≥16 points from baseline to Week 8, was determined; comparisons between UPA dosage groups and PBO were based on Cochran-Mantel-Haenszel tests and missing data were reported using non-responder imputation.

Results: A total of 250 patients with mean age 42.3 years, 60% male, and mean UC duration 8 years were analysed. At baseline, mean IBDQ was 125. EQ-5D visual analogue scale (VAS) was 53. SF-36 Physical Component Summary (PCS) was 42, SF-36 Mental Component Summary (MCS) was 41, FACT-F was 29, WPAI activity impairment was 52%, and overall work impairment was 51%.

Significant improvements in all PROs were consistently observed as early as Week 2 in patients receiving 45 mg QD (p < 0.05). At Week 8, IBDQ response was reported by significantly more patients taking UPA (67%, 62%, and 77% for 15, 30, and 45 mg QD, respectively) than PBO (35%) (all p < 0.05). For patients treated with UPA compared to PBO, significant improvements from baseline to Week 8 were reported in IBDQ score, EQ-5D VAS, and SF-36 PCS for all UPA doses (all p < 0.05; Table). Significant improvements were also shown for FACT-F and overall work impairment and activity impairment in 15, 30, and 45 mg QD (Table).

Introduction
5-aminosalicylic acid (5-ASA) is the mainstay of treatment of patients with ulcerative colitis (UC). 5-ASA acts locally in the colonic mucosa and its mucosal concentrations inversely correlated to disease activity (1–4). Previous studies suggest that treatment with Asacol (pH-dependent formulations) (1, 2) is more effective than Mezavant and Pentasa (time-dependent release formulation) (1, 5). However the different 5-ASA formulations (1–4) were included. 8 hours after ingestion of mesalazine, mean mucosal concentration of 5-ASA and its inactive metabolite acetyl-5-ASA were measured. Disease activity was assessed by Mayo score (MS) and IBDQ improvement was assessed using a mixed model repeated measures (MMRM) analysis. The percentage of patients at Week 12 with clinical response, endoscopic healing, and IBDQ improvement ≥16 were also assessed.

Results
Aims and Methods: In this cross-sectional non-randomized study, we have measured mucosal concentration of 5-ASA and its inactive metabolite acetyl-5-ASA in the left hemicolon of patients with quiescent ulcerative colitis using the Inflammatory Bowel Disease Questionnaire (IBDQ) and evaluated using a mixed model repeated measures (MMRM) analysis. The percentage of patients at Week 12 with clinical response, endoscopic healing, and IBDQ improvement ≥16 were also assessed.

Conclusion: Patients using Mezavant had significantly higher mucosal 5-ASA concentrations than patients using Pentasa, despite higher endoscopic MS. There was small intra-individual variations, but large inter-individual variations in mucosal 5-ASA concentrations in the left hemicolon of patients with UC using oral mesalazine preparations.

Disclosure: Nothing to disclose.

P0309 COMPARATIVE FREQUENCY OF CLOSTRIDIAL INFECTION IN PATIENTS WITH ULCERATIVE COLITIS RECEIVING MESENCHYMAL STROMAL CELLS AND BIOLOGICAL PREPARATIONS

O Kayazev1, A Kaghammadova1, A Lishchinskaya1, I Donchenko1, A Parfenov1, N Fadeeva1, M Zvyaglov1
1Moscow Clinical Scientific Center, Inflammatory Bowel Diseases, Moscow, Russian Federation
2Moscow Clinical Scientific Center, Moscow, Russian Federation

Introduction: Patients with inflammatory bowel disease (IBD) experienced more frequent development of Clostridial infection and much higher rates of morbidity and mortality compared to patients without IBD. Risk factors are immunosuppressive therapy.

Aims and Methods: The aim is to compare the frequency of Clostridial infection (CI) in patients with ulcerative colitis (UC) receiving bone marrow mesenchymal stromal cells (MSC) and biological therapy.

Materials and methods. The patients were divided into 3 groups: the first group (n = 23) received the MSCs culture according to the scheme (0-12 weeks), then every 26 weeks; the second group of patients with UC (n = 23) received infliximab (IFX) in combination with azathioprine (AZA) according to the recommended scheme, the third group received only IFX according to the scheme. The toxins A and B of Clostridium difficile were determined by the enzyme immunoassay in the stools. The comparative analysis was carried out using the method of 4-field tables using nonparametric statistical criteria.

Results: In patients of the 1st group, toxin A was detected in 2/23 patients (4.3%), in the 2nd group - in 2/23 patients (9.5%) (RR - 0.44, 95% CI 0.06-4.3, x2 - 0.06, p > 0.05), in the third - in 2/23 patients (9.5%) (RR - 0.44, 95% CI 0.06-4.3, x2 - 0.06, p > 0.05). In patients of the 1st group toxins A and B were not detected - 0/23 (0.0%), in the 2nd group toxins A and B were detected in 1/21 (3%) patients (x2 - 0.59, p > 0.05, and x2 - 0.52, p > 0.006) respectively.

Conclusion: The frequency of Clostridial infection in patients with ulcerative colitis receiving mesenchymal stromal cells is significantly lower than in patients with ulcerative colitis receiving biological immunosuppressive preparations.

Disclosure: Nothing to disclose.
INTRODUCTION

We demonstrated similarity of efficacy, safety and pharmacokinetics of CT-P13 and INX in phase 2 randomized control trial in moderate to severe Crohn's disease (CD) patients (1). Recent studies suggested an association between higher infliximab trough concentrations and better clinical outcomes in the treatment of inflammatory bowel disease (2), which has to be examined in a prospective observation. Note. Lower limit of quantitation of serum Infliximab concentration was 0.55 µg/ml.

Aims and Methods: This post-hoc analysis of the CT-P13 3.4 study (NCT02098681) aimed at determining whether earlier Ctrough might be used as a predictor of subsequent clinical remission. A total of 198 patients who underwent efficacy analysis at Week 54 and had PK parameters at Week 6 (pre-dose concentration at Week 14) and Week 14 (pre-dose concentration at Week 22) were included in this analysis. All PK parameters were analyzed while the patients received INX or CT-P13 at 5 mg/kg with no dose escalation until week 22. Mann-Whitney U test was used to analyze the difference of Ctrough levels in patients achieving or not achieving clinical response at Week 54, and between CT-P13 and INX treatment groups among responders. Receiver operating characteristic (ROC) curves were constructed for sensitivity (S) and specificity (Sp) analyses of Ctrough levels at Week 54.

RESULTS: Median Week 6 Ctrough levels were 3.7 and 3.6 µg/ml, and Week 14 Ctrough levels were 2.6 and 2.2 µg/ml in the CT-P13 and INX groups, respectively. Ctrough levels were significantly higher (p < 0.01) in Week 54 responders (CDAI < 150) than in non-responders in both CT-P13 and INX treatment groups. Since overall Ctrough levels in responders were not significantly different between CT-P13 and INX treatment groups (p > 0.05), both groups were pooled for further analysis. While Week 6 Ctrough could be much more sensitive to predict clinical success (specificity > 90%) than Week 6. Suggested diagnostic cut-offs to predict clinical remission were Ctrough > 4.5 µg/ml at Week 6, and Ctrough level > 4.0 µg/ml at Week 14 as a predictor of subsequent clinical remission. In addition, Week 14 levels appear to be more specific to predict one year outcome than Week 6 levels.

(FX: 5mg/kg every 8 weeks, ADA: 40mg every other weeks) and confirmed tolerability of ED were allocated to ED group. All administered elemental diet 9000kcal/day or more. Other patients were allocated to Non-ED group. Primary endpoint was the cumulative remission rate at 2 years after baseline. CDAI was calculated at each visit during 2 years after baseline. Clinical relapse defined as ≥20 points in CDAI and/or need for additional treatment including dose escalation of Anti-TNF and surgery. Adherence of ED was confirmed by clinician’s interview to patients at each visit and amount of prescriptions.

Results: 88 patients were enrolled and 16 patients were excluded due to no response of Anti-TNF induction therapy. Of the 72 patients, 37 were allocated to ED group and 35 subjects were allocated to Non-ED group. As for clinical features, previous enteral nutrition was more frequent observed in ED group (p = 0.03). The cumulative remission rate at 2 years was no significant difference between ED group (60.9% in ED group, 56.7% in Non-ED group, p = 0.98). By a multivariate analysis, intestinal stricture (HR: 5.0, 95% CI: 1.6–15.2), previous steroid therapy (HR: 4.0, 95% CI: 1.1–14.9) and CRP > 5mg/L (HR: 6.5, 95% CI: 1.8–24.4) at baseline were risk factors of clinical relapse. Adherence of ED in ED group was relatively low and only 11 patients had been kept 9000kcal/day or more of ED.

Conclusion: Additional power of ED for CD patients who responded to initial Anti-TNF induction therapy could not be confirmed. Efficacy of concomitant ED in clinical settings such as loss of response need to be clarified in the future. Moreover, improvement of adherence might be important in order to obtain clinical efficacy of ED.

Disclosure: Nothing to disclose.

P0343 EARLY OPTIMIZATION OF GOLUMUMBDE DOSES INDUCES DELAYED RESPONSE AND LONG-TERM CLINICAL BENEFIT IN ULCERATIVE COLITIS

C Alba1, M Martínez-Montiel2, M.M Bosca-Watts3, S Rubia4, O Nantes5, R Higuera6, F Bertoletti7, P Macigliano8, M Sierra-Ausín9, N Mancenido9, J.L Pezo-Calle10, AAlgaba10, D Olivares10, C Taxonera,11

Introduction: Data assessed outcomes of glucocorticoid monotherapy (GLM) dose optimization in patients with ulcerative colitis (UC) are lacking. According to the summary of product characteristics by the European Medicines Agency (EMA) patients with body weight less than 80 kg received GLM maintenance doses of 50 mg q2wk at week 2, followed by week 6 (3). The benefit of GLM dose escalation from 50 mg q4wk to 100 mg q4wk has not been evaluated in clinical practice.

Aims and Methods: The aim of this study was to evaluate outcomes of early optimization of GLM from 50 mg q4wk to 100 mg q4wk in UC patients with adequate response to GLM induction treatment. This observational multicentre cohort study included consecutive UC patients without response to GLM induction doses, in which weight-based GLM maintenance doses of 50 mg q2wk were administered (57.1%), and 1 of the 2 steroid refractory cases. On average remission was sustained for 8.6 months in steroid naive patients and for 10.4 months in steroid dependent (57.1%), and 1 of the 2 steroid refractory cases. On average remission was sustained for 8.6 months in steroid naive patients and for 10.4 months in steroid dependent cohort. Mucosal biopsies revealed that infiltrating leukocytes were mostly neutrophils and monocytes. There was a marked reduction of infiltrating leukocytes in the biopsies from the responder patients. Patients with extensive deep UC lesions together with loss of the mucosal tissue at the lesions were non-responders. Patients with the first UC episode were identified as the best responder (4). Patients' demographic features should guide to select responder patients.

Results: We evaluated 24 UC patients with body weight below 80 kg, 18 (75%) were female, 18 (75%) had extensive colitis and 5 (20%) left-sided colitis. The mean age of the patients was 47 (standard deviation 14), and the median disease duration was 9.5 years (interquartile range [IQR] 4–14). 14 patients (58%) had previous anti-TNF failure (4 infliximab, 2 adalimumab and 8 both). All patients received induction with GLM 200 mg/100 mg at weeks 0 and 0 and 2. In all patients GLM 50 mg q4wk was optimized to 100 mg q4wk, starting at week 6 in 10 patients and at week 10 in 14 patients. At week 14, 16 of 24 patients (67%; 12 with corticosteroid-free) recovered clinical response. Of these, 4 patients (%) achieved corticosteroid-free remission. After a median follow-up of 12 months (IQR 10–22), 13 of 24 patients (54%) avoided GLM failure. 13 of 16 patients (81%; all but 1 were corticosteroid-free) who achieved delayed response at week 14 recovered clinical benefit with GLM 100 mg q4wk at last follow-up. Eleven of 24 patients (46%) had GLM failure. Reasons for GLM discontinuation were nonresponse at week 14 in 8 patients (37%) and secondary loss of response in 3 patients (27%) who had delayed response at week 14. None of the patients experienced adverse events leading to GLM withdrawal. All 24 patients avoided colectomy at last follow-up. None of the patients were dose-de-escalated to GLM 50 mg q4wk.

Conclusion: Early optimization of GLM from 50 mg q4wk to 100 mg q4wk induces delayed response (by partial Mayo score) at week 14 in two thirds of UC patients with body weight below 80 kg who were non-responders to GLM induction. Continuing GLM 100 mg q4wk in patients who do not demonstrate an early clinical response to GLM induction but achieve a delayed response was safe and leads to long-term clinical benefit.

P0344 BASELINE DEMOGRAPHIC FEATURES OF ULCERATIVE COLITIS PATIENTS AS PREDICTORS OF CLINICAL RESPONSE TO ADSORPTIVE DEPLETION OF MYELOID LINEAGE LEUKOCYTES AS REMISSION INDUCTION THERAPY

T Tanaka1, H Goshin1, T Ishibori2, T Kajihara3, T Miura4

1Akita Prefectoral Hospital, Dept. of Gastroenterology, Hiroshima, Japan
2Akita Prefectoral Hospital, Internal Medicine, Hiroshima, Japan

Contact E-Mail Address: tomatom@akio-do.jp

Introduction: Inflammatory bowel disease (IBD) is associated with elevated myeloid lineage leukocytes, which show activation behaviour (1) including the CD14+CD16+DR++ phenotype known as proinflammatory monocytes and a major source of tumour necrosis factor-a (2). Accordingly selective depletion of myeloid leukocytes by granulocyte/monocyte apheresis (GMA) with a CDAI has been expected to promote remission and enhance drug efficacy. However, hitherto studies in IBD have reported contrasting efficacy outcomes, ranging from an 85% (3) to a statistically insignificant level (4). Patients’ demographic features should guide to select responder patients.

Aims and Methods: In a single-centre retrospective setting, we looked at the baseline clinical and endoscopic features of responders and non-responders to adsorptive GMA in 145 consecutive ulcerative colitis patients who had undergone GMA as remission induction therapy. 73 patients were steroid naive, 70 were steroid dependent, and 2 were steroid refractory. Patients had received up to 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her or his own control. Clinical activity index (CAI) >4 was defined as remission. Biopsies from endoscopically detectable inflamed mucosa were processed to see the impact of GMA on leucocytes within the mucosa.

Results: At entry, the average CAI was 12.8, range 10–17; 93 patients (64.1%) had responded to GMA, 52 of 73 steroid naive (71.2%), 40 of 70 steroid dependent (57.1%), and 1 of the 2 steroid refractory cases. On average remission was sustained for 8.6 months in steroid naive patients and for 10.4 months in steroid dependent cohort. Mucosal biopsies revealed that infiltrating leukocytes were mostly neutrophils and monocytes. There was a marked reduction of infiltrating leukocytes in the biopsies from the responder patients. Patients with extensive deep UC lesions together with loss of the mucosal tissue at the lesions were non-responders. Patients with the first UC episode were identified as the best responder (4). Patients’ demographic features should guide to select responder patients. Patients with extensive deep ulcers, with long duration of UC refractory to multiple pharmacologics are unlikely to benefit from GMA. In therapeutic settings, knowing baseline features, which may identify responder patients should help to avoid futile use of medical resources.

Disclosure: Nothing to disclose.

References
Introduction: Anti-tumour necrosis factor alpha (anti-TNF) therapies are effective and widely used in the management of patients with inflammatory bowel disease (IBD). However, they may induce a drug-induced lupus ‘syndrome’, recently termed anti-TNF induced lupus (ATIL). The widely accepted diagnostic criteria for this syndrome being (1) a temporal relationship between symptoms and anti-TNF therapy and resolution of symptoms following cessation of the offending medication, (2) at least one serologic American College of Rheumatology criteria of systemic lupus erythematosus (SLE), either a positive ANA or anti-dsDNA, and (3) at least one non-serological criteria such as arthritis, serositis or rash (1). ATIL is increasingly recognised and described in the rheumatology literature, however, data on the true prevalence of ATIL in IBD populations due to lack of recognition of the condition as well as difficulty making a diagnosis as there is significant overlap in symptoms with the extraintestinal manifestations of IBD.

Aims and Methods: To evaluate the incidence, clinical and serological markers, as well as risk factors for developing ATIL, in an IBD population. A retrospective observational cohort study of all IBD patients that completed induction as well as at least one maintenance dose of anti-TNF therapy (infliximab or adalimumab) at Royal Perth Hospital between January 2008 and December 2017. A diagnosis of ATIL was confirmed based on the criteria outlined above. Demographic, clinical and serological parameters were obtained from electronic and paper records.

Results: 154 ATIL treatment courses with anti-TNF therapy (30 infliximab and 124 adalimumab) were included. 17 (5.7%) patients that received infliximab and 1 patient (0.6%) on adalimumab developed ATIL. Patients that developed ATIL were more likely to be older at commencement of anti-TNF (46.47 years ± 13.79 years vs. 43.75 years, p = 0.027) and were more likely to be female (72.2%), antidi-SLE (21.1%), anti-Smith antibodies (marker for idiopathic SLE) (16.7%), anti-Ro/SSA antibodies (marker for systemic lupus erythematosus) (10.5%) and anti-dsDNA (marker for drug induced lupus) (10.5%). ANA was positive in 22 patients (46.9%) with results ranging from 7 to 30 IU/ml. In those patients who had a baseline ANA performed prior to commencing anti-TNF therapy (14 patients), the ANA level increased compared with their baseline level. Other serological markers that developed ATIL included anti-dsDNA in 105 (67%), anti-histone antibodies (marker for drug induced lupus) 2/15 (13%), anti-Smith antibodies (marker for idiopathic SLE) 0/15 (0%), Rheumatoid Factor (autoimmune arthritis) 0/8 (0%) and anti-CCP (Rheumatoid arthritis) 0/5 (0%).

Conclusion: Our study suggests, IBD patients with varying doses and durations during their anti-TNF course. The mean duration of anti-TNF therapy till development of ATIL was 19.78 months ± 15.76 months. The most common clinical symptom was polyarthitis in 15 patients (83.3%) with rash occurring in 5 patients (27.8%). All patients with a diagnosis of ATIL demonstrated an elevated ANA with results ranging from 7 to 30 IU/ml. In those patients who had a baseline ANA performed prior to commencing anti-TNF therapy (14 patients), the ANA level increased compared with their baseline level. Other serological markers that developed ATIL included anti-dsDNA in 105 (67%), anti-histone antibodies (marker for drug induced lupus) 2/15 (13%), anti-Smith antibodies (marker for idiopathic SLE) 0/15 (0%), Rheumatoid Factor (autoimmune arthritis) 0/8 (0%) and anti-CCP (Rheumatoid arthritis) 0/5 (0%).

Unification of IBD Management Across Countries: Are There Differences Among China, India, and the United States

Aim: To compare the differences in medical and surgical management of inflammatory bowel disease (IBD) across China, India, and the United States.

Methods: This study included IBD patients recruited from three major IBD centers in China, India, and the United States. Demographic, clinical, and medication use data were collected using a standardized questionnaire. Logistic regression analyses were performed to determine the factors associated with differences in medical and surgical management.

Results: The study included 300 IBD patients from China, 200 from India, and 300 from the United States. There were significant differences in the use of medications and surgical interventions across the countries. For example, the use of biologics was higher in the United States compared to China and India. The odds of undergoing surgery for Crohn’s disease were higher in India compared to the United States. The odds of using corticosteroids were similar across the three countries.

Conclusion: There are significant differences in the medical and surgical management of IBD across China, India, and the United States. Further research is needed to identify the underlying reasons for these differences and to develop strategies to improve the management of IBD worldwide.

Introduction: Upadacitinib (UPA) is an oral selective Janus kinase 1 inhibitor that is being assessed in patients with ulcerative colitis (UC). In addition to the symptoms captured in the Mayo score, the effects of UPA on other patient-reported UC symptoms including bowel urgency and abdominal pain were evaluated in the double-blind placebo-controlled dose-ranging 8-week induction portion of the phase 2b/3 study (U-ACHIEVE [NCT02819635]).

Aims and Methods: Adult patients with active UC (Adapted Mayo score [Mayo score without Physician Global Assessment] ≤ 5–9 points and centrally-read endoscopy subscore 2–3) who had inadequate response or intolerance to corticosteroids, immunosuppressants, or biologics were randomized to the modified-release formulation 7.5, 15, 30, or 45 mg once daily (QD) UPA or PBO (1:1:1:1:1) for 8 weeks. UC symptoms including bowel urgency (yes/no) and abdominal pain (0–none, 1–mild, 2–moderate, 3–severe) were collected in the patient daily diary. The total number of days with bowel urgency, average score of abdominal pain, Mayo rectal bleeding subscore (RBS), and stool frequency subscore (SFS) over the most recent 3-consecutive days prior to the study visits were calculated. The proportion of patients who reported no bowel urgency and abdominal pain score = 0 (which were considered the most stringent endpoints), along with RBS = 0 and SFS ≤ 1 at week 8, respectively, were compared between UPA and PBO groups using the Cochran-Mantel-Haenszel test adjusted for previous biologic use, baseline corticosteroid use, and baseline Adapted Mayo score ≤7 and >7. Non-responder imputation was used for missing values. Sensitivity analyses were conducted by excluding patients with no bowel urgency or those with none to mild abdominal pain (average abdominal pain score ≤1) at baseline.

Results: A total of 250 patients with mean age 42.3 years, 60% males, and mean UC duration 8 years were analysed. At baseline, 83% of subjects reported 3 days with bowel urgency and 41% of subjects had an average abdominal pain score ≤ 1. As early as week 2, more UPA-treated patients reported no bowel urgency over the 3 days and less abdominal pain compared with PBO. At week 8, significantly higher proportions of patients reported no bowel urgency over the 3 days; abdominal pain score = 0, RBS = 0, and SFS ≤ 1 in most UPA groups compared with the placebo group with a potential dose effect across the 7.5 mg, 15 mg, 30 mg, and 45 mg QD dose groups (Table). In the sensitivity analyses, the risk difference between UPA groups and PBO was similar to the primary analyses when excluding patients with no bowel urgency, or excluding those with none to mild abdominal pain at baseline.***, **, *, *statistically significant at 0.001, 0.01, 0.05, and 0.1 level for treatment vs PBO.

Patients with no bowel urgency at baseline were excluded.

Results: Financial support for the study was provided by AbbVie. AbbVie participated in interpretation of data, review, and approval of the abstract. NRI: Non-responder imputation

Clinical remission per adapted Mayo: stool frequency subscore ≤ 1, rectal bleeding subscore of 0, and endoscopic subscore ≤ 1

Endoscopic improvement: endoscopic subscore ≤ 1

Clinical remission per full Mayo: full Mayo score ≤ 2 with no subscore > 1

Clinical response per adapted Mayo: decrease from baseline in the adapted Mayo score ≥ 2 points and ≥ 30% from baseline, PLUS a decrease in rectal bleeding subscore (RBS) ≥ 1 or an absolute RBS ≤ 0

Endoscopic remission: endoscopic subscore of 0.

[Table Exposure-Response Model-Predicted Efficacy Endpoints at Week 8 In Subjects with UC for Different Upadacitinib Regimens*]

*Simulation for 200 replicates, each with 600 subjects (400:200 upadacitinib:placebo) per dosing regimen. The 90% prediction intervals (5th/95th percentile) reflect the impact of random sampling of subjects and model parameters point estimates (i.e. prediction intervals do not reflect the model parameter uncertainty.).

Introduction: Genome-wide association studies revealed that single nucleotide polymorphisms within the gene encoding protein tyrosine phosphatase non-receptor type 2 (PTPN2) are associated with the onset of inflammatory bowel diseases (IBD) and other chronic inflammatory disorders. PTPN2 is involved in maintaining intestinal homeostasis in vivo via regulating inflammatory signalling pathways and protecting intestinal epithelial barrier function. Previously, we have shown that spermidine, a naturally occurring polyamine, exerts anti-inflammatory effects in mouse colitis models and treated in the same manner. mRNA expression of IFNG, PTPN2, ICAM1 (which encodes for intercellular adhesion molecule 1) and NOD2 (encoding for nucleotide-binding oligomerization domain-containing protein 2) was analysed in both experiments by performing quantitative-PCR.

Results: IFN-γ treatment resulted in increased mRNA expression of ICAM1, PTPN2 and NOD2 genes in all cells. Of interest, however, in cells expressing CT genotype, basal mRNA expression of those genes was already elevated, and their mRNA expression level following IFN-γ treatment was clearly higher than those observed in PTPN2 wild-type cells. In line with this, cells carrying the CT variant showed reduced PTPN2 activity in basal and IFN-γ treated conditions. Activation of PTPN2 by spermidine clearly reduced IFN-γ-induced elevation of ICAM1, IFNG and NOD2 expression in T84 and HT29 cell lines (p < 0.05). Despite initially elevated IFN-γ responses, spermidine treatment was more effective in HT29 cells expressing the CT variant (p < 0.05), resulting in elevated activation of PTPN2, and more pronounced reduction of ICAM1, INFG and NOD2 mRNA expression in all cell types (TT; n = 5), as well as from healthy controls (all TT; n = 5) and treated in the same manner. mRNA expression of IFNG, PTPN2, ICAM1 (which encodes for intercellular adhesion molecule 1) and NOD2 (encoding for nucleotide-binding oligomerization domain-containing protein 2) was analysed in both experiments by performing quantitative-PCR.

Conclusion: Spermidine treatment effectively reduced inflammatory response in T84 and HT29 cell lines and in PBMC from IBD patients. Reduction of the inflammatory responses is more pronounced in case of the presence of C (variant) allele in PTPN2 SNP rs1893217 carriers. Taken together our data indicates that spermidine might be a new promising therapeutic agent in IBD treatment, furthermore the presence of the PTPN2 C allele might serve as a good prediction marker for treatment response.

P0350 VEDOLIZUMAB IN REFRACTORY MICROSCOPIC COLITIS: AN INTERNATIONAL CASE SERIES

P Riviere1, A Münch2, P Michetti3, N Chande4, G De Hertogh5, P Schoeters6, M Ferrante7, S Vermeire8, G Van Assche9

1University Hospitals Leuven, Department of Gastroenterology, Leuven, Belgium
2Aix-Marseille University, Faculty of Health Sciences, Laboratory of Experimental Gastroenterology, Aix-Marseille University, France
3University of California, Division of Gastroenterology, San Diego, United States
4IQVIA, RWI, London, United Kingdom
5University of California, Division of Gastroenterology, San Diego, United States

Aims and Methods: We solicited gastroenterologists in Europe and Canada for cases of MC treated with vedolizumab. All patients had histologically proven MC. Vedolizumab 300 mg IV was administered at weeks 0, 2 and 6, and then every 8 weeks. Clinical remission and histological remission were defined as < 3 stools per day and normalization of histology, respectively.

Results: Eleven cases were evaluated for analysis from 4 referral centers in 4 different countries [9 females, median age at diagnosis 49 years, lymphocytic colitis (LC) n = 5, collagenous colitis (CC) n = 6]. Median (IQR) disease duration at vedolizumab initiation was 51 (29–70) months and median stool frequency was 8 (6–10) per day. All patients had previously failed second-line therapy. Patients had also been exposed to mesalamine (5/11), cholestyramine (5/11), azathioprine (6/11), methotrexate (3/11) and 10/11 had failed at least 1 anti-TNF agents (8/11 infliximab, 5/11 adalimumab, 1/1 golimumab). Reasons for anti-TNF cessation were inefficacy (8/10), loss of response (1/10) and delayed infusion reaction (1/10). After 3 infusions of vedolizumab, clinical remission was observed in 5/11 patients (2 LC and 3 CC) of whom 3 remained well with maintenance therapy (median duration of 13 months). Vedolizumab was stopped due to intolerance in 1 patient (post-infusion hypertensive crisis) and loss of response for 1 patient. Biopsies after induction were obtained from 9/11 patients. Histological remission was observed in 3/4 patients with clinical remission 2/3 CC, 1/1 LC and 0/5 patients without clinical improvement. Rescue therapies in failure were budesonide (n = 1), systemic steroids (n = 1), methotrexate (n = 1), experimental drug (n = 1) and loop-ileostomy (n = 1).

Conclusion: In a series of highly refractory microscopic colitis patients, vedolizumab induced clinical remission in 5/11 subjects and disappearance of histological inflammation in 3/4. Larger randomized trials are needed to assess the efficacy of vedolizumab in patients with MC.

P0351 DEFINING ‘EARLY DISEASE’ IN INFLAMMATORY BOWEL DISEASE: THE RESULTS OF A SYSTEMATIC LITERATURE REVIEW

L Peyrin-Biroulet1, J Jairath1, D Wright2, A Lloyd2, D Denham2, S Campbell-Hill3, P S Dulai3

1Nancy University Hospital Inserm U954 Dept. of Hepato-Gastroenterology, Department of Gastroenterology, Vandoueuvre les Nancy, France
2Western University, Department of Medicine, Division of Gastroenterology, London, Canada
3Takeda Pharmaceuticals International, London, United Kingdom
4University of California, Division of Gastroenterology, San Diego, United States

Aims and Methods: The Cochrane library, MEDLINE and EMBASE were searched using key words and indexing terms. Eligible papers reported the characteristics and/or treatment (ts) of adult pts (≥18 years) with ‘early’ inflammatory bowel disease (IBD) from clinical or observational studies published January 2008 - March 2018. There was no intervention or comparator restriction and no assumption on the definition of ‘early’. Papers published before 2008, not in English, in paediatric or non-IBD pts were excluded. Uncertainty as to study eligibility was reconciled by a second independent reviewer.

Results: The SLR returned 1,742 abstracts; 107 papers (16 clinical studies; 91 observational studies) met inclusion criteria. A mean 6.2 papers per year (yr)
were published 2008–2012 and 16.0/yr in 2013–2017. ‘Early disease’ was explicitly defined in 33 papers (19 CD; 7 UC; 1 CD and UC; 6 IBID overall) 22 (67%) used time since diagnosis (DX) only; 9 (27%) combined this with DX history; 1 (3%) DX history and symptom duration; and 1 (3%) DX history and time since first IBID prescription. Definitions in UC used time since DX only (6 papers), combined with DX history and symptom duration (1 paper). Cut-off points for time since DX were applied in 30 papers: ≤3 months (20%), 3–6 months (17%), 6–12 months (27%), 1–2 yrs (17%) and >2 yrs (20%). Definitions based on DX history specified pts should be immunomodulator (IMM) and biologic naive (7 papers) or additionally corticosteroid (CS) naive (4 papers). ‘Early disease’ pt characteristics were stratified by CD and UC. Median disease duration ranged between 0.2–10.6 yrs in CD and 1.1–5.4 yrs in UC. CD cohorts included pts with stricturing (max 64%), penetrating (max 48%) or fistulising disease (max 14%). Disease and prior surgery (max 51%); UC cohorts included pts with pancolitis (max 100%) and prior surgery (max 69%) (see Table). ‘Early’ CD cohorts met the consensus criteria (disease duration <18 months and IMM and biologic naive) in only 2 papers published since 2012. Conclusion: The characteristics of ‘early’ CD and UC pts have increasingly come under focus as the concept of early intervention in IBID has gained traction. Early disease has predominantly been defined by time since DX (± other variables) but the disease duration of ‘early’ cohorts can be very long. Often ‘early’ pts already have complex disease, which may mean the ‘window of opportunity’ for intervention is missed. The consensus definition of ‘early’ CD has not been consistently applied since being developed. Robust definitions of early CD and UC are required to accurately evaluate the potential of early biologic tx to improve outcomes.

P0352 LACK OF EARLY RESPONSE AND MUCOSAL HEALING IS ASSOCIATED WITH COLEYTECTOMY IN PATIENTS WITH MODERATE TO SEVERE UC. A MULTICENTRIC REAL-WORLD OUTCOME STUDY

Data from ulcerative colitis (UC), uncontrolled inflammation may result in disease progression requiring colectomy. Mucosal healing (MH) has been associated with avoidance of colectomy (1). The pursuit of mucosal healing (MH) has been associated with a reduction in disease progression requiring colectomy. Mucosal healing (MH) was defined in 33 papers (19 CD; 7 UC; 1 CD and UC; 6 IBID overall) 22 (67%) used time since diagnosis (DX) only; 9 (27%) combined this with DX history; 1 (3%) DX history and symptom duration; and 1 (3%) DX history and time since first IBID prescription. Definitions in UC used time since DX only (6 papers), combined with DX history and symptom duration (1 paper). Cut-off points for time since DX were applied in 30 papers: ≤3 months (20%), 3–6 months (17%), 6–12 months (27%), 1–2 yrs (17%) and >2 yrs (20%). Definitions based on DX history specified pts should be immunomodulator (IMM) and biologic naive (7 papers) or additionally corticosteroid (CS) naive (4 papers). ‘Early disease’ pt characteristics were stratified by CD and UC. Median disease duration ranged between 0.2–10.6 yrs in CD and 1.1–5.4 yrs in UC. CD cohorts included pts with stricturing (max 64%), penetrating (max 48%) or fistulising disease (max 14%). Disease and prior surgery (max 51%); UC cohorts included pts with pancolitis (max 100%) and prior surgery (max 69%) (see Table). ‘Early’ CD cohorts met the consensus criteria (disease duration <18 months and IMM and biologic naive) in only 2 papers published since 2012. Conclusion: The characteristics of ‘early’ CD and UC pts have increasingly come under focus as the concept of early intervention in IBID has gained traction. P0353 VEDOLIZUMAB OUTCOMES IN REAL-WORLD BIO-NAIVE ULCERATIVE COLITIS AND CROHN’S DISEASE PATIENTS (EVOLEVA): IN TREATMENT PATTERNS, CLINICAL EFFECTIVENESS AND SAFETY

Introduction: Vedolizumab (VDZ), a gut-selective humanised immunoglobulin G1 monoclonal antibody that binds to α4β7 integrin, is indicated in Canada for the treatment (Tx) of moderately-to-severely active ulcerative colitis (UC;19 May 2015) and Crohn’s disease (CD;19 May 2016). Real-world data on Tx patterns, clinical effectiveness and safety outcomes in biologic (bio)-naive patients treated with VDZ in Canada are limited. Aims and Methods: A retrospective cohort study was conducted in adult (>18 years) UC and CD patients who were bio-naive and newly initiated VDZ between 19 May 2015 and 31 Dec 2016. Real-world data on Tx patterns, clinical effectiveness and safety outcomes in biologic (bio)-naive patients treated with VDZ in Canada are limited.

Introduction: The role of gut microbiota in inflammatory bowel disease (IBD) pathogenesis is established and fecal microbiota transplantation (FMT) has shown some efficacy inducing remission in active ulcerative colitis in three randomized controlled clinical trials (RCT) to date. However there is no RCT result included while in flare (Harvey Bradshaw index [HBI] ≥ 4) and treated with oral corticosteroid. Following clinical remission (HBI < 5), patients were randomized to receive either FMT (50–100g of stool from a single donor suspended in 250–350mL of physiological serum) or sham transplantation (physiological serum) during a colonoscopy. Corticosteroids were tapered and a Sorensen index defined by a receiver’s fecal microbiota at week 6 closer to the donor (with a Sorensen index ≥0.6 [Sorensen index = 1- Bray Curtis index]) than to the patient before FMT. Clinical, biological and endoscopic efficacy endpoints were also evaluated (NCT02097797).

Results: Overall, 21 patients were randomized, 8 received donor FMT, 9 received sham-transplantation and 4 were ineligible for transplantation (3 because of patient identification and 1 for unavailability of donor). In the FMT group, none of the patients reached the primary endpoint. However, patients from the FMT group had a microbiota composition at 6 weeks closer to donors compared to patients in the Sham-transplantation group (p = 0.016). The steroid-free clinical remission rate at 10 and 24 weeks were 44.4% and 33.3% in the Sham-transplantation group and 87.5% and 57.1% in the FMT group (p = 0.13 and p = 0.6 respectively at week 10 and 24). CDEIS decreased 6 weeks after FMT (8.5 [4.6;13.0] vs. 3.5 [1.0;8.9]; p = 0.03) but not after Sham-transplantation (2.4 [0.6;8.3] vs. 2.7 [0.7;10.0]; p = 0.8). Conversely, CRP level increased 6 weeks after Sham-transplantation (3.0 [3.0;4.2] vs. 6.9 [4.0;8.7] mg/L; p = 0.008) but not after FMT (3.0 [3.0;3.0] vs. 3.0 [3.0;14.2] mg/L; p = 0.5). Failure to achieve steroid-free clinical remission at week 24 in FMT group was associated with absence of donor microbiota engraftment at week 6 and with the absence of increase in alpha diversity. The microbiota composition at week 6 was predictive of steroid-free clinical remission at week 24. No safety signal was identified.

Conclusion: None of the patients reached the primary endpoint related to the level of implantation of the donor microbiota. However, this pilot study in CD suggests that FMT performed after achieving clinical remission by corticosteroids could be effective as a maintenance treatment. A larger randomized control trial is now required to confirm the efficacy of this strategy.

Disclosure: Nothing to disclose
Results: 359 from 426 patients have so far been analysed (F = 153 [42.6%], UC = 160 [44%], CD = 190 [53%], indeterminate/other colitis = 9 [3%]). Mean duration on thiopurines was 5.7 years. Mean disease duration was 12.7 years. Out of 359 IBD patients on thiopurines, 275 (77%) had 6-TGN levels measured at some stage. 177/275 (64%) had therapeutic levels, whilst 98/275 (36%) did not. 166/275 (60.5%) were in clinical remission. 94/275 (34.5%) were Not for. For 15 patients (5%), no data was available. Of those that had therapeutic levels of 6-TGN, 112/177 (63%) were in clinical remission, 19/112 (17%) were in total remission (clinical, biochemical [normal CRP/WCC], endoscopic and histological). 60/112 (55%) were on Azathioprine (AZA), 48/112 (43%) were on mercaptopurine (6MP). For 4/112 (4%) patients there was no thiopurine treatment or the treatment was stopped. 46/112 (41%) were on combined therapy with biologics. Of those that had non-therapeutic levels of 6-TGN, 54/98 (55%) were in clinical remission. 13/54 (24%) were in total remission. 37/54 (68%) AZA, 15/54 (28%) 6MP, 2/54 (4%) data not complete/purines were stopped. 24/54 (44%) were on combined therapy with biologics. Of those with therapeutic levels of 6-TGN, 53/177 (30%) were not in clinical remission. 30/53 (57%) AZA, 22/53 (41%) 6MP, 1/53 (2%) patient data not complete/purines were stopped. 41/53 (77%) were on combined therapy with biologics. Of the cohort that had non-therapeutic levels of 6-TGN, 41/98 (42%) were not in clinical remission. 21/41 (51%) AZA, 15/41 (37%) 6MP, 5/41 (12%) data not complete/purines were stopped. 29/41 (71%) were on combined therapy. (Note: 12 of the 177 patients with therapeutic 6-TGN had no data on remission status. 3 of the 98 patients with non-therapeutic levels of 6-TGN had no data on remission status).

Conclusion: Our study so far suggests that in IBD patients on thiopurines (sole or combined therapy), clinical remission rates were similar (63% vs. 55%) for those with therapeutic levels and for those that had either not achieved therapeutic levels of 6-TGN, 55% of patients were still in clinical remission. Moreover, there is no significant relationship between achieving therapeutic 6-TGN levels and clinical remission when looked separately for clinical remission. Moreover, there is no significant relationship between achieving therapeutic 6-TGN levels and clinical remission when looked separately for clinical remission. Moreover, there is no significant relationship between achieving therapeutic 6-TGN levels and clinical remission when looked separately for clinical remission. Moreover, there is no significant relationship between achieving therapeutic 6-TGN levels and clinical remission when looked separately for clinical remission.

Introduction: Strictures are a common complication of Crohn's disease (CD) and may develop in all segments of the gastrointestinal (GI) tract. While coloscopy has been proven safe and effective for balloon dilation therapy of GI-associated strictures of the ileocecum (1,2), the published evidence on efficacy and safety of balloon-assisted endoscopy (BAE) for balloon dilation therapy of CD strictures of the small intestine is scarce. We therefore performed a combined efficacy and safety analysis based on all published studies of BAE for small intestinal strictures available in the literature.

Aims and Methods: A formal systematic literature review was performed to access all relevant citations found in Embase, Medline and the Cochrane library regarding BAE used for EBD of small intestinal stricture. In addition, conference proceedings including Digestive Disease Week 2010-2017, European Crohn’s and Colitis Foundation 2011-2017, United European Gastroenterology Week 2013-2016, Gastroenterology 2016-2017, German Gastroenterology Congress 2013-2017 were screened for additional data. Available technical and clinical variables were extracted from all studies available for a descriptive pooled data analysis. With this data, we were able to analyse the following:

Results: 18 publications with a total of 445 CD patients and 773 performed dilation procedures were included. 19.3% were anastomotic strictures. Technical success rate was 88.1%, resulting in clinical efficacy in 78% of patients. Major complications with regard to dilation, defined as perforation, bleeding or dilation-related surgery, occurred in 3.7% of all procedures. During a median follow-up period of 16 months, 45.7% of patients reported symptomatic recurrence, while 38.1% of patients needed to undergo re-dilation and 27.5% required surgery. Currently, there is no study available investigating the recurrence, while 38.1% of patients needed to undergo re-dilation and 27.5% required surgery. During a median follow-up period of 16 months, 45.7% of patients reported symptomatic recurrence, while 38.1% of patients needed to undergo re-dilation and 27.5% required surgery. During a median follow-up period of 16 months, 45.7% of patients reported symptomatic recurrence, while 38.1% of patients needed to undergo re-dilation and 27.5% required surgery. During a median follow-up period of 16 months, 45.7% of patients reported symptomatic recurrence, while 38.1% of patients needed to undergo re-dilation and 27.5% required surgery. During a median follow-up period of 16 months, 45.7% of patients reported symptomatic recurrence, while 38.1% of patients needed to undergo re-dilation and 27.5% required surgery. During a median follow-up period of 16 months, 45.7% of patients reported symptomatic recurrence, while 38.1% of patients needed to undergo re-dilation and 27.5% required surgery. During a median follow-up period of 16 months, 45.7% of patients reported symptomatic recurrence, while 38.1% of patients needed to undergo re-dilation and 27.5% required surgery. During a median follow-up period of 16 months, 45.7% of patients reported symptomatic recurrence, while 38.1% of patients needed to undergo re-dilation and 27.5% required surgery.

Conclusion: For dilation therapy of CD-associated strictures of the small intestine possesses a high rate of short-term technical and clinical success and may represent an alternative to surgery in stricturing CD. BAE-associated complication rates appear comparable to those related to dilation therapy of ileocecal stricture during colonoscopy. Larger, controlled studies are warranted to further evaluate BAE for dilation therapy of CD strictures of the small intestine.

P0359 LONG-TERM SAFETY, EFFICACY AND PHARMACOKINETICS OF THE ANTI-MADCAM-1 MONOCLONAL ANTIBODY SHP647 IN CROHN'S DISEASE: THE OPERA II STUDY

G.R D’Haens1
1 Universiteit Hospital Schleswig-Holstein, Christian-Albrechts-University, Kiel, Germany

Contact E-Mail Address: g.dhaens@amc.uva.nl

Introduction: The endothelial adhesion protein MAdCAM-1 is a promising novel drug target in inflammatory bowel disease; the fully human IgG2 anti-MAdCAM-1 monoclonal antibody SHP647 is in development for induction and maintenance of remission in patients with Crohn’s disease (CD) and ulcerative colitis.

Aims and Methods: OPERA II was a multicentre, open-label, phase 2 extension study (NCT01298492), designed to assess the long-term safety and efficacy of SHP647 in patients with moderate-to-severe CD. Eligible patients had completed 12 weeks’ induction treatment (placebo or 22.5 mg, 75 mg or 225 mg s.c. SHP647) in OPERA I (NCT01276509), or had a clinical response (≥3-point decrease in Harvey Bradshaw Index score) to 225 mg SHP647 in the open-label study, TOSCA (NCT01387594). Patients received SHP647 (75 mg, s.c.) every 4 weeks from baseline to week 72, and were followed up for safety assessments monthly for a further 24 weeks. Dose de-escalation to 22.5 mg owing to intolerance/treatment-emergent adverse events (TEAEs), or escalation to 225 mg owing to clinical deterioration/poor response, was allowed as judged by the investigator. Primary endpoints were frequency of TEAEs, TEAEs leading to withdrawal and SAXEs. Concentrations of serum SHP647, high-sensitivity C-reactive protein (hsCRP) and faecal calprotectin (FC) were assessed as secondary endpoints.

Results: Of the 268 patients who enrolled and entered the treatment period, 149 completed the study. Table 1 shows the proportions of patients experiencing TEAEs, TEAEs leading to withdrawal and serious adverse events (SAEs). The most common treatment-related TEAEs in the treatment period were arthralgia (6.0%), nasopharyngitis (5.6%) and headache (5.2%). 2 patients died: 1 during treatment (75 mg) of multiple organ failure after postoperative asphyxia following a resection of the terminal ileum (female, 30 years, SHP647 75 mg) and 1 during follow-up due to metastatic adenocarcinoma (unknown primary; male, 36 years, SHP647 225 mg); neither death was considered drug-related. No patients de-escalated their dose, and 157 patients increased their dose to 225 mg SHP647 after a median time of 28 weeks. Serum trough concentrations of SHP647 averaged 7051 ng/mL at week 4 and remained constant over time with a steady-state concentration of 7300 mg/mL at week 72. 3 months after dose escalation to 225 mg, patients achieved a new steady-state level of 16190 mg/mL, which is consistent with the pharmacokinetics determined previously. Patients whose dose escalated appeared to have more severe disease, with higher hsCRP (24.12±6.23 mg/L) and FC (2771.5±3293 mg/kg) levels at baseline than patients who remained on 75 mg, who had hsCRP and FC levels of 19.12±24.33 mg/L and 1232.1±2378 mg/kg, respectively. Concentrations of hsCRP decreased gradually over time from week 0 to 72; the pattern was similar in patients who received 75 mg and those who escalated to 225 mg, though at the end of the study, patients who had escalated their dose had higher values than those who had not.

Conclusion: SHP647 75 mg (with potential dose escalation to 225 mg) was generally well-tolerated in patients with Crohn’s disease over 72 weeks. These results add to evidence for the long-term safety of SHP647. [Table 1. All-cause and treatment-related adverse events in the treatment and follow-up periods.]

**P0360** FMT CAPSULES DECREASE FECAL CALPROTECTIN AND IMPROVE SYMPTOMS IN ULCERATIVE COLITIS PATIENTS - A PILOT STUDY

F Côté1,2, S Günther1, P Brown2, A Petersen2, S J Halkjær1, L Hansen1, A H Christensen1
1Aleris-Hamlet Hospital, Department of Medical Gastroenterology; Søborg, Copenhagen
2Copenhagen University Hospital Hvidovre, Gastroent, Medical Division; Hvidovre, Denmark

**Contact E-Mail Address:** frederickod422@hotmail.com

**Introduction:** There is growing evidence indicating that gut ‘dysbiosis’ is one of the factors in the pathogenesis of Inflammatory Bowel Disease (IBD). Fecal microbiota transplantation (FMT) from healthy donors is an effective treatment of recurrent *Clostridium difficile* infections both when administered by endoscopy or through oral capsules (2). In this study we aimed to be promising in Ulcerative Colitis remission induction (3). However long-term safety and effects on ulcerative colitis remain unclear.

**Aims and Methods:** The aim was to test if multi-donor FMT capsules, manufactured at the laboratory at Aleris-Hamlet Hospital, Copenhagen, could lower Fecal (F) Calprotectin and improve symptoms in patients with Ulcerative Colitis and to test the safety of the treatment.

7 patients, aged 27 to 51 years, with Ulcerative Colitis, a Simple Clinical Colitis Index (SCAI) between 4 and 10, and F-Calprotectin > 250 mg/kg were treated with 25 multi-donor FMT capsules daily for 50 days as a supplement to each individual patient’s stable dose of standard treatment throughout the period of intervention. The 4 fecal donors were healthy individuals who were screened according to current guidelines (4) and recruited through postings in the area around the hospital. Participants were followed with fecal samples and SCAI throughout the study period. We used Mann-Whitney U tests to compare F-Calprotectin and SCAI levels at each time-point after baseline with the levels at baseline.

**Results:** Median F-Calprotectin at baseline was ≥1800 mg/kg (the upper limit for Calprotectin at our laboratory was 1800 mg/kg). After 4 weeks of treatment F-Calprotectin decreased to 6 of the 7 participants and there was a significant decrease in median F-Calprotectin of 912 mg/kg (p = 0.004). 1 week after the intervention had stopped, at 8 weeks from baseline, the median decrease in F-Calprotectin from baseline of 551 mg/kg was no longer statistically significant (p = 0.14).

The participants had a median SCAI of 6 at baseline. After both 4 and 8 weeks all participants had lowered their SCAI and there was a significant decrease in median SCAI of, respectively, 5 (p = 0.001) and 6 (p = 0.001).

All participants completed the treatment and no serious adverse events were registered throughout the study period.

**Conclusion:** Daily multidonor FMT-capsules were safe and significantly lowered F-Calprotectin in Ulcerative Colitis patients with SCAI between 4 and 10 after 4 weeks of active treatment. The participants also experienced a significant improvement in symptoms throughout the study period.

FMT administered in various forms appears promising in the treatment of Ulcerative Colitis but many questions remain. In particular, the type of FMT administered in various forms appears promising in the treatment of recurrent *Clostridium difficile* infections both when administered by endoscopy or through oral capsules (2). In this study we aimed to be promising in Ulcerative Colitis remission induction (3). However long-term safety and effects on ulcerative colitis remain unclear.

**P0361** POPULATION PHARMACOKINETIC AND PHARMACODYNAMIC ANALYSIS OF SHP647, A FULLY HUMAN MONOCLONAL ANTIBODY AGAINST MUCOSAL ADDRESSIN following repeated subcutaneous (SC) administration of 7.5, 22.5, 75, and 225 mg every 4 weeks was performed to identify sources of variability and support dosing in adult patients with UC/CD. A total of 440 patients were included in the analysis, of whom 249 (56.6%) had UC and 191 (43.4%) had CD. Population PK analysis of SHP647 nec and model fitting was performed for apparent linear and/or linear elimination. Covariate analysis was performed using a step-wise covariate approach. The following covariates were explored: age, sex, markers of renal and liver function (i.e., creatinine clearance, bilirubin, AST, ALT) as well as renal impairment categories (normal, mild, moderate, severe disease (UC/CD), anti-drug antibody (ADA), free MacAdCAM-1 levels and various laboratory measurements (C-reactive protein [CRP], albumin, fecal calprotectin, and colonoscopy score). PK and PD analyses were performed using NONMEM.

**Results:** Patients with UC/CD presented with similar mean age (40.4 and 36.0 years, respectively) and body weight (72.5 kg and 70.6, respectively). SHP647 was very well tolerated in patients with UC/CD. A 2-compartment model with linear and non-linear eliminations was fitted in an adequate characterization of concentration-time profiles. An empirical allometric function was used on clearance and volume parameters. The absorption of SHP647 was described with a first-order rate constant of absorption (Ka) and absorption lag time. Population estimates of apparent clearance (CL/F) volume of distribution (V/F), and volume of distribution (V/F) were 0.0127 L/h (0.305 L/day) and 6.53 L, respectively. The CL/F was mainly dependent on baseline CRP and albumin while V/F was mainly dependent on body weight. No covariates were observed in patients with UC/CD. ADA was not identified as a covariate explaining the variability of CL/F. The Michaelis-Menten constant (KM) was very low (19.0 ng/mL) suggesting that the non-linear elimination (target-mediated) occurred at very low concentrations, and was less likely to contribute significantly to elimination half-life at therapeutic concentrations and under steady state conditions. The apparent SHP647 half-life associated with average steady state concentrations for the 7.5, 22.5, 75, and 225 mg dose levels were 7.04, 12.3, 16.5 and 18.6 days, respectively. A linear PK/PD model was used to describe the relationship between concentrations of SHP647 and the median change in calprotectin. Based on minimum concentrations of SHP647 under steady state conditions, the 75 and 225 mg doses were associated with >95% suppression of circulating MacAdCAM-1 levels.

**Disclosure:** Y Wang is an employee of Shire. JF Marier is a paid consultant of Certara. N Kassir is a paid consultant of Certara. P Martin is an employee of Shire.
patients in induction, TOFA 10mg BID had the greatest efficacy (60% and 18%) and had >99% probability of having better efficacy compared with ADA (36% and 7%). Among RR trials, TOFA had the greatest efficacy (5mg BID: 71% and 54%; 10mg BID: 72% and 56%) and had a 70–99% probability (depending on the comparator) of having better efficacy than other agents in the TNFi-naive subgroup. TOFA 10mg BID had the greatest efficacy (61% and 49%) and a 72–79% probability of having better efficacy than other agents in the TNFi-exposed subpopulation. Results among TT trials were similar. The probability of TOFA having better efficacy than other agents was 83–98% and 67–91% for TNFi-naive and TNFi-exposed, respectively.

Conclusion: Except compared with IFX in the TNFi-naive induction setting, TOFA has similar or superior efficacy compared with biologics as induction and maintenance therapy for moderately-to-severely active UC.

Introduction: Up to one-third of patients with acute severe Ulcerative Colitis (ASUC) will fail intravenous corticosteroids (IVCT) treatment, requiring rescue therapy with Cyclosporin (Cy), Infliximab (IFX) or colectomy. Although several scores for predicting response to IVCT exist, formal comparison is lacking.

Aims and Methods: This was a retrospective cohort single-center study. The endoscopic Mayo score and the Oxford, Edinburgh and Lindgren scores were determined at admission and on the 3rd day of IVCT treatment, respectively. Outcomes included prediction of steroid refractoriness, need for rescue medical therapy and surgery.

Results: From 489 patients with Ulcerative Colitis, 112 presented with ASUC; 58% were male with a median age of 33.5 years (range 18–80). The median of Truelove and Witts score was 4 (range 2–35). 35% of patients showed an incomplete or absent response to IVCT, 28.6% received rescue medical therapy (65.6% with IFX, 31.3% with Cy and 3.1% received sequential therapy with Cy and IFX) and 13.4% were colectomized up to 1 year from admission. The Lindgren score was also a better predictor of the need of colectomy than the Edinburgh, Oxford and endoscopic Mayo scores in predicting steroid refractoriness, need for rescue medical therapy and colectomy.

P0364 RISK OF VENOUS THROMBOEMBOLISM BY DISEASE ACTIVITY, HOSPITALIZATION, AND SURGERY IN INFLAMMATORY BOWEL DISEASE: A NATIONWIDE COHORT STUDY

Contact E-Mail Address: tjkim@samsung.com

Introduction: Risk of venous thromboembolism (VTE) of inflammatory bowel disease (IBD) patient is higher than general population. Guidelines recommend primary prophylaxis of venous thromboembolism for certain periods. However, little is known about the magnitude of the risk of VTE development in these periods. We estimated the risk of VTE during a hospitalized flare, a non-hospitalized flare, a hospitalization without flare, IBD-related surgery, and other major surgeries.

Aims and Methods: Using the National Health Insurance claims data for the entire Korean population, we included 33,131 patients with IBD from January 2012 until December 2013 with 198,825 age- and sex-matched controls, and followed up until December 2016. We used Cox regression models to identify whether the risk of VTE varies by hospitalization, disease flare, surgery and/or presence of other risk factors.

Results: Of 33,131 patients with IBD and 198,825 matched controls, 110 patients and 376 controls developed VTE. The overall VTE risk was higher in patients with IBD than controls with [adjusted hazard ratio (aHR), 2.10; 95% confidence interval (CI), 1.70–2.61], compared to controls. The risk of VTE during a non-hospitalized flare of IBD patients was higher compared with controls (aHR, 3.14; 95% CI, 1.90–5.19). The risks of VTE were increased much more during a hospitalization with non-flare (aHR, 16.23; 95% CI, 10.71–24.58) and a hospitalized flare (aHR, 27.20; 95% CI, 19.40–49.65). The risk of VTE was highest at the time of IBD-related surgery (aHR, 39.66; 95% CI, 9.87–159.33). Also, the risk at the time of other major surgeries was increased (aHR, 15.59; 95% CI, 7.73–31.43).

Conclusion: The prophylaxis of VTE for Asian patients with IBD should be considered at the time of a hospitalized flare and IBD-related surgery. However, the prevention of VTE is not needed for non-hospitalized patients with flare.

Introduction: The need for surgery and hospital admission in newly diagnosed inflammatory bowel disease (IBD) patients in the biological era is largely unknown.

Aims and Methods: i) To assess the frequency of surgery and hospital admission in an inception cohort of adults newly diagnosed with IBD. ii) To describe the characteristics and indications for surgical interventions; and iii) to evaluate the causes of hospital admissions.

Prospective and population-based nationwide study in Spain. Adult patients diagnosed with IBD’s disease (CD), ulcerative colitis (UC) or indeterminate colitis (IC) - during 2017 in the 17 Spanish regions were included and followed-up for 12 months after diagnosis. Data were captured in a web-based database (AEG-REDCap).

Results: 3,469 incident cases from 116 centres covering approximately 50% of the Spanish population were included. Of them, 53% were males, with mean age of 43 years. At baseline 50% had UC, 45% CD, and 5% IC. About 14% of patients had a family history of IBD. CD patients, 55% had ileal and 26% ileocolonic location, and 11% perianal disease. In UC patients, 34% had extensive colitis and 52% pan-colitis. In CD patients, 55% had ileal and 26% ileocolonic location, and 11% perianal disease. In UC patients, 34% had extensive colitis and 52% pan-colitis. In CD patients, 55% had ileal and 26% ileocolonic location, and 11% perianal disease. In UC patients, 34% had extensive colitis and 52% pan-colitis.

Conclusion: In this large nationwide inception cohort in the biological era, surgery was not more frequent among CD patients with perianal disease than in those without it (34 vs. 5.2%, p < 0.001). Other variables, such as family history of IBD, or smoking habit were not associated with the need of surgery. A total of 892 patients (26%) had 1,038 hospital admissions during follow-up, with disease diagnosis as the main indication (71.2%). Among them, 53% were males, with mean age of 43 years. At baseline 50% had UC, 45% CD, and 5% IC. About 14% of patients had a family history of IBD. CD patients, 55% had ileal and 26% ileocolonic location, and 11% perianal disease. In UC patients, 34% had extensive colitis and 52% pan-colitis. In CD patients, 55% had ileal and 26% ileocolonic location, and 11% perianal disease. In UC patients, 34% had extensive colitis and 52% pan-colitis. In CD patients, 55% had ileal and 26% ileocolonic location, and 11% perianal disease. In UC patients, 34% had extensive colitis and 52% pan-colitis. In CD patients, 55% had ileal and 26% ileocolonic location, and 11% perianal disease. In UC patients, 34% had extensive colitis and 52% pan-colitis. In CD patients, 55% had ileal and 26% ileocolonic location, and 11% perianal disease. In UC patients, 34% had extensive colitis and 52% pan-colitis. In CD patients, 55% had ileal and 26% ileocolonic location, and 11% perianal disease. In UC patients, 34% had extensive colitis and 52% pan-colitis.

P0366 SHORT TERM AZATHIOPRINE CO-TREATMENT DOES NOT IMPACT LONG TERM CLINICAL OUTCOME IN INFLAMMATORY BOWEL DISEASE TREATED WITH INFlixIMAB, BUT HAS INFlixIMAB-SPARING EFFECT

Introduction: It is usual clinical practice to start infliximab as combination treatment with azathioprine in patients with inflammatory bowel disease (IBD) and to de-escalate from combination treatment to infliximab (IFX) monotherapy once disease remission is reached. It is however unclear if the addition of azathioprine during introduction of IFX improves long-term clinical outcomes and pharmacokinetics in patients who previously failed azathioprine.

Aims and Methods: We aimed to study the effect of short-term (6–12 months) co-treatment with azathioprine on long-term clinical outcome and on consumption of IFX in patients who escalated from azathioprine to either IFX monotherapy or to combination of azathioprine and IFX due to inefficacy of azathioprine. We included 149 patients (94 Crohn’s disease, 55 ulcerative colitis) who started IFX between 2011 and 2016 for active IBD in a tertiary referral centre. To study the effect of azathioprine co-treatment we compared patients who started IFX as combination treatment with azathioprine and then de-escalated to IFX monotherapy with patients who started IFX as monotherapy from the beginning (IFX mono).

Results: The study population included 78 (52%) IFX combo patients and 71 (48%) IFX mono patients. IFX combo (Crohn’s disease: ileocolonic 71%, perianal 42%; ulcerative colitis: pancolitis 62%) and IFX mono (Crohn’s disease: ileocolonic 74%, perianal 29%; ulcerative colitis: pancolitis 69%) groups did not differ in disease phenotype.

During a median follow-up of 19 months [interquartile range (IQR): 12–40 months] 149 patients (43.3%) underwent 188 surgical interventions: 131 (83.8%) in CD and 18 (9.0%) in UC (p < 0.001). Regarding the first surgical procedure, 60% were urgent and 60% entailed abdominal surgery (30% for perforation, 28% for stenosis and 26% for abdominal abscess). CD patients with inflammatory behaviour had lower rates of surgery than those with stricture or fistula (5.6%, 14%, and 32%, respectively, p < 0.001). Surgery was also more frequent among CD patients with perianal disease than in those without it (34 vs. 5.2%, p = 0.001). Other variables, such as family history of IBD, or smoking habit were not associated with the need of surgery. A total of 892 patients (26%) had 1,038 hospital admissions during follow-up, with disease diagnosis as major driver (81%). Median time from diagnosis to admission was 0 months (range 0–9 months). Reasons for hospital admissions are summarized in table 1. Conclusion: In this large nationwide inception cohort in the biological era, a substantial proportion of IBD patients underwent surgery, which was urgent in over 2/3 of the cases. Strictureting and fistulizing complications in CD patients were the main drivers for surgery in these patients. 1/4 of patients were hospitalized – most of them at disease diagnosis – within the first 3 months follow-up.

[Table 1. Reasons for hospital admissions during follow-up.]

**P0367 MAINTENANCE OF REMISSION WITH TOFACITINIB IN PATIENTS WITH ULCERATIVE COLITIS: SUBPOPULATION ANALYSIS FROM AN OPEN-LABEL, LONG-TERM EXTENSION STUDY**

1Jeil School of Medicine at Mount Sinai, New York, NY, United States
2Medical University of Vienna, Vienna, Austria
3Penn Presbyterian Medical Center, Philadelphia, PA, United States
4Pfizer Inc, Collegeville, PA, United States

**Contact E-Mail Address:** walter.reinsch@meduniwien.ac.at

**Introduction:** Tofacitinib is an oral, small molecule JAK inhibitor that is being investigated for ulcerative colitis (UC). The efficacy and safety of tofacitinib were demonstrated in 3 Phase (P) 3, randomised, placebo-controlled studies (OCTAVE Induction 1, NCT01465763; OCTAVE Induction 2, NCT01458951; OCTAVE Sustain, NCT01458574) in patients (pts) with moderate to severe UC. An ongoing P3, multicentre, open-label, long-term extension study (OLE; NCT01470612) included pts from OCTAVE Induction 1 or 2, or OCTAVE Sustain.

**Aims and Methods:** We present an update (as of 10 Nov 2017) of previous analyses of the OLE study maintenance remission subpopulation (pts in remission [total Mayo score ≤ 2, no individual subscore >1, rectal bleeding subscore of 0] at Wk [Wk] 52 of OCTAVE Sustain). Pts in remission at Wk 52 of OCTAVE Sustain received tofacitinib 5 mg twice daily (BID) in the OLE study. Efficacy data, including remission, mucosal healing (Mayo endoscopic subscore of 0 or 1), clinical response (decrease from induction baseline total Mayo score ≥ 30%, and ≥ 50%, and decrease in rectal bleeding subscore ≥1 or absolute rectal bleeding subscore of 0 or 1; all based on local read) and partial Mayo score (PMS) remission (PMS ≤ 2, no individual subscore >1), up to Month 24 of the OLE study (as observed and with non-responder imputation), are presented for pts in remission after tofacitinib in OCTAVE Sustain. Safety data are reported for all pts who received tofacitinib 5 mg BID in the OLE study.

**Results:** Of 944 pts who received ≥1 dose of study drug in the OLE study, 163 (mean age: 45 years; 46.0% female) were in remission at Wk 52 of OCTAVE Sustain (NCT01458574). Efficacy over 24 months was similar irrespective of tofacitinib dose previously received in OCTAVE Sustain. Among all pts receiving tofacitinib 5 mg BID in the OLE study, 78.9% reported treatment-emergent AEs (TEAEs). Serious and severe AEs occurred in 12.0% and 8.0% of pts, respectively. The most frequent TEAEs by preferred term were *nasopharyngitis* and *worsening of UC*. 5 pts (2.9%) had serious infections and 10 (5.7%) had herpes zoster (all mild or moderate severity). Malignancy excluding non-melanoma skin cancer was reported in 1 (0.6%) pt (lung cancer).

**Conclusion:** The majority of pts with moderate to severe UC who achieved remission after 52 wks of tofacitinib 5 mg in OCTAVE Sustain maintained remission, mucosal healing, clinical response and PMS remission with tofacitinib 5 mg BID for up to 24 months in the OLE study (up to 3 years from maintenance study baseline). No new safety risks were identified.

**Disclosure:** J-F Colombel has received research support from AstraZeneca, Ferring, Schering-Plough, UCB, and consultancy and/or lecture fees from Abbott, ActoGeniX, Albioreo Pharma, Amgen, AstraZeneca, Bayer AG, Biogen Idec (BI), BMS, Cellerix, Centocor, Celltrion, ChemoCentryx, Covance, Danone, Dr Falk, Eli Lilly, Ferring, Galapagos, Genentech, Gilead, Grunenthal, ICON, Immunodiagnostik, InDex Pharmaceuticals, Inova, Jansen, J&J, Kyowa Hakko Kirin, Lipid Therapeutics, MedImmune, Millennium, Mitsubishi Tanabe, MSD, Novartis, Oceia, Otsuka, PDL, Pfizer Inc, Pharmacosmos, Procter & Gamble, Prometheus, Roberts Clinical Trials, Schering-Plough, Second Genome, SetPoint Medical, Shire, Takeda, Therakos, TiGenix, UCB, Vifor, Yakult, Zentiva, 4SC; MT Osterman has received consultancy fees from AbbVie, Jansen, Lycera, MedImmune, Novo Nordisk, Takeda, UCB; AJ Thorpe and research support from UCB; C.I Nduaka, H Zhang, N Lawyend, G.S Friedman, C Su are Pfizer Inc employees and shareholders.

**Introduction:** Tofacitinib is an oral, small molecule Janus kinase inhibitor that is being investigated for ulcerative colitis (UC). The efficacy and safety of tofacitinib was demonstrated as induction and maintenance therapy in patients (pts) with moderate to severe UC to achieve UC in 3 Phase (P) 3, randomised, placebo-controlled studies. Safety and efficacy of tofacitinib for UC are being evaluated in an ongoing, open-label, long-term extension (OLE) study.

**Aims and Methods:** We present an update (as of 10 Nov 2017) of previously presented safety and efficacy data of an ongoing P3, multicentre, OLE study (NCT01470612) in pts who completed or demonstrated treatment failure in OCTAVE Sustain (NCT01458574) or were non-responders in OCTAVE Induction 1 or 2, or OCTAVE Sustain. Pts in remission (total Mayo score ≤ 2, no individual subscore >1, rectal bleeding subscore of 0) at Wk 52 of OCTAVE Sustain (per local read) were assigned to receive tofacitinib 5 mg daily BID in the OLE study. Pts under went endoscopy, and induction non-responders were mandated to withdraw if they did not show a clinical response. Efficacy end points were derived from Mayo Clinic scores per local read.

**Results:** Of 944 pts who received ≥1 dose of study drug (for up to 4.9 years), 769 (81.5%) pts received tofacitinib 10 mg BID; 326 (34.5%) pts discontinued due to insufficient clinical response, and 65 (6.9%) pts discontinued due to adverse events [AEs] excluding worsening UC. Serious and severe AEs occurred in 14.8% and 9.9% of pts, respectively. The most frequent treatment-emergent AE (TEAE) classes were infections and gastrointestinal disorders. The most frequent TEAEs were nasopharyngitis, worsening UC and increased blood creatine phosphokinase. Serious infections were reported in 5 (2.9%) and 23 (3.0%) pts, herpes zoster in 10 (5.7%) and 47 (6.1%) pts, and major adverse cardiovascular events in 1 (0.6%) and 1 (0.1%) pts in the 5 and 10 mg BID groups, respectively. Malignancies excluding non-melanoma skin cancer (NMSC) were reported in 1 pt (0.6%) and 1 pt (2.3%) and NMSC in 4 (2.3%) and 9 (1.2%) pts, in the 5 and 10 mg BID groups, respectively (with no clustering of malignancy type). No new safety risks were identified. Available remission, mucosal healing and clinical response data up to Month 24 are shown (Table).

**Conclusion:** In pts with moderate to severe UC in the OLE study, no new safety risks emerged compared with those observed with tofacitinib in rheumatoid arthritis. Efficacy data from the OLE study continue to support long-term efficacy with tofacitinib 5 or 10 mg BID up to 24 months beyond Wk 52 of OCTAVE Sustain.

*Patients in remission, based on central endoscopic reading, at Wk 52 of OCTAVE Sustain (all receiving tofacitinib 5 mg BID in OLE study); †Patients were treated as non-responders after the time of discontinuation up to the visit they would have reached if they had stayed in the study. No imputation for missing data was applied for ongoing patients. All values are per local read of endoscopy, unless otherwise stated (baseline values are per central read). Remission was defined as a total Mayo score ≤2 with no individual subscore >1, and rectal bleeding subscore of 0; mucosal healing was defined by a Mayo endoscopic subscore ≤1; PMS remission was defined as a PMS ≤2 with no individual subscore >1.

BID, twice daily; n, number of patients in the maintenance remission subpopulation with the specified response within the given category; N, number of randomised patients in the maintenance remission subpopulation; N1, number of patients in the remission subpopulation who could have reached the specified time point (based on enrolment date and last non-missing total Mayo score [endoscopy for mucosal healing]; NRI, non-respondent imputation; OLE, open-label long-term extension; PMS, partial Mayo score; Wk, Week.

**Aims and Methods:** Aim of this study has been to investigate its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients seven year after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985-2016, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2–2.5 mg/kg.

**Results:** Out of 2802 consecutive IBD outpatients visited in the index period, AZA was prescribed to 433 patients, 236 (54.5%) were affected by Crohn’s disease (CD) and 197 (45.5%) by ulcerative colitis (UC). 179 patients with a follow-up < 84 months were excluded from the study. 254 patients were evaluated, 141 (55.5%) with CD and 113 (44.5%) with UC. 139 (54.7%) were male patients referred in our Institution, between 1985–2016, were reviewed and all

**Summary of safety and efficacy in the OLE study**
and 115 (45.3%) female (average age of 35.62 ± 14.20 SD years, range 14–74 y.). 7 years after the institution of treatment, 127 (50%) patients still were in steroid-free remission (83 CD vs 44 UC, 58.8% and 38.9%, respectively, p = 0.0024), 71 (27.9%) had a relapse requiring retreatment with steroids (29 CD vs 42 UC, 20.6% and 37.2%, respectively, p = 0.0047), 56 (22.1%) discontinued the treatment due to side effects (29 CD vs 27 UC, 20.6% and 23.9%, respectively). Loss of response from 1st to 7th year of follow-up was low, about 20%.

**Conclusion:** 7 year after the onset of treatment 50% of patients did not require further steroid courses. After the first year loss of response was low in 6 subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.

**Introduction:** To evaluate the efficacy of granulocyte and monocyte apheresis (GMA) in corticosteroids naive patients with active ulcerative colitis (UC) without concomitant corticosteroids therapy in remission induction and sustained remission.

**Aims and Methods:** In this multicenter retrospective study, ninety corticosteroids naive patients with active UC received GMA as remission induction therapy between 2012 and 2018 in 4 Japanese institutes were enrolled. Each patient received weekly or intensive (2–3 sessions/week) GMA up to 11 sessions. Partial Mayo score <2 meant remission, while ≤1 in Mayo endoscopic subscore meant mucosal healing. Concomitant medication with corticosteroids, biologics or calcineurin inhibitors were not allowed, but medication with 5-ASA and immune-modulators were permitted.

**Results:** The overall remission and mucosal healing rates were 71.1% (64/90) and 64.5% (49/76), respectively. Subjects who achieved a remission were clinically and endoscopically followed for 12 months after a course of GMA. After 12 months follow up, a sustained remission was recorded in 66.7% (44/66) of those treated with GMA. The patients who had obtained a remission after a course of GMA showed relapses up to 33.3% (22/66) and mean time to relapse was 10.0 months.

**Conclusion:** The overall remission and mucosal healing rates were 71.1% (64/90) and 64.5% (49/76), respectively. Subjects who achieved a remission were clinically and endoscopically followed for 12 months after a course of GMA. After 12 months follow up, a sustained remission was recorded in 66.7% (44/66) of those treated with GMA. The patients who had obtained a remission after a course of GMA showed relapses up to 33.3% (22/66) and mean time to relapse was 10.0 months.

**Introduction:** The introduction of anti-TNF therapy has dramatically changed the treatment of refractory inflammatory bowel disease (IBD-Crohn’s disease [CD], ulcerative colitis [UC]). However, the clinical use of anti-TNF therapies is limited by loss of response posing significant challenge for clinicians. Therapeutic drug monitoring has gained increasing popularity in the management of IBD. However, relationship between clinical outcomes and serum anti-TNF levels is complex and controversial in many cases.

**Aims and Methods:** The aim of this study is to simultaneously analyse the serum, mucosal and fecal calprotectin and adalimumab levels, to determine the mucosal expression of TNF-α and to assess the relationship between the levels of anti TNF-α in a matched samples with endoscopic and clinical activities of IB patients receiving anti-TNF maintenance therapy.

**Results:** Data of 34 patients have been analyzed (20 CD, 14 UC; 17 infliximab, 17 adalimumab). The number of TNF-α positive cells was significantly higher in mucosal samples of active vs. inactive part of the bowel (p < 0.001). Mucosal drug level proved to be significantly higher in samples obtained from the inactive vs. active part of the bowel (p = 0.001). However, no association could be detected between the number of TNF-α positive cells and either endoscopic activity or mucosal drug levels. Serum drug level was significantly lower in patients who developed anti drug antibody (p = 0.043). We did not find any correlation between serum drug level and fecal calprotectin concentration, however, calprotecint level was higher in patients with anti-drug antibody positivity (p = 0.0134). No correlation was detected between serum and mucosal anti TNF levels.

**Conclusion:** Our study was the first that simultaneously examine serum, tissue and fecal concentrations of anti TNF-α comparing with clinical and endoscopic activities. We were unable to find evidence against the hypothesis of no association between serum drug levels and mucosal anti TNF-α concentration. However, the sample size is currently very low, and more data is needed to be collected in order to better understand the association between blood and tissue drug levels or disease activity. Nevertheless, it is hoped that these measurements will allow a better overview of the drug distribution and clearance and may help to identify a useful surrogate marker of clinical and endoscopic activity.

**Disclosure:** Nothing to disclose.

**P0374 ANTI-TNF VS. CONVENTIONAL TREATMENT FOR THE PREVENTION OF POSTOPERATIVE RECURRENCE OF CROHNS DISEASE: A META-ANALYSIS**
A Er o o1, N Farkas1, P Pejggi1, G Verde1, J Bajkor1, E Erős1,1, P Sarlos1,2

**Contact E-Mail Address:** adreannhat@gmail.com

**Introduction:** The majority of patients with Crohn’s disease (CD) need surgery during their lifetime. Within 1 year, 80% of the operated patients has endoscopic postoperative recurrence (POR). However, there is no widely accepted consensus on the prevention of POR.

**Aims and Methods:** Our aim was to compare the efficacy of biological agents and that of conventional therapy as prophylactic therapy options for POR and also to compare the efficacy of prophylactic biological treatment in high risk vs. non-risk group of patients. Studies were identified through searching EMBASE, and Web of Science for English-language studies published from inception up to 15 April 2017. The PICO items were, as follows: (P) adults with CD who had intestinal resection, (I) biological therapy (adalimumab, infliximab), (C) conventional therapies (mesalamine, thiopurines and placebo), and (O) clinical, endoscopic, and severe endoscopic POR. Patients were considered at ‘high risk’ for POR if they had ≥1 of the following risk factors: active smoking, young age at diagnosis, penetrating or perianal disease at diagnosis, ≥1 resections, and resection within 3 years. Odds ratios (OR) and 95% confidence intervals (CI) were calculated. PROSPERO registration number is CRD42017083679.

**Results:** The data of 2 observational and 8 randomized controlled trials, including 709 CD patients, were analysed. Anti-TNFα agents were significantly more effective in preventing clinical and endoscopic POR compared to conventional therapies (OR: 0.501, 0.319–0.786, p = 0.003, and OR: 0.157, 0.069–0.359, p < 0.001, respectively). We could demonstrate an overall benefit of biological therapy in unselected patient groups of CD patients regarding clinical, endoscopic and severe endoscopic POR (OR: 0.449, 0.272–0.741, p = 0.002; OR: 0.132, 0.055–0.317, p < 0.001, and OR: 0.263, 0.085–0.817, p = 0.021, respectively). In the course of direct comparison, there was no significant difference in POR rates between the 2 anti-TNF agents. Patients previously treated with biologicals were less likely to maintain remission after surgery (OR: 0.509, 0.303–0.853, p = 0.010).

**Conclusion:** Compared to the conventional therapies, biological agents are more effective in preventing clinical and endoscopic POR both in unselected and high-risk patients. In addition, biologicals should be considered for surgery in patients with preoperative anti-TNF therapy to maintain remission.

**Disclosure:** Nothing to disclose.

**P0375 EFFICACY AND SAFETY OF GRANULOCYTE ADSORPTION APERHERESIS IN ELDERLY PATIENTS WITH ULCERATIVE COLITIS**
A Ito, S Murasugi, T Omori, K Tokushige
Tokyo Womens Medical University, Dept. medicine, Inst. Gastroenterology, Tokyo, Japan

**Contact E-Mail Address:** itoayumi@m.ge.tmu.ac.jp

**Introduction:** The number of elderly patients with ulcerative colitis (UC) has been increasing. Elderly UC patients differ from younger patients with respect to the course of their disease, response to treatment, risk of adverse effects, and influence of UC on the quality of life. At our hospital, granulocyte adsorption apheresis (GAA) is often used to treat elderly UC patients.

**Methods:** The study included 80 patients evaluated. We divided them into an elderly group (aged ≥75 years) and a younger group (< 65 years old), and then we compared the groups’ (1) clinical characteristics, (2) the efficacy and adverse effects of CAP, and (3) the complications of PSL therapy.

**Results:** The remission rate was 78.8% in the elderly group and 87.5% in the younger group, and CAP demonstrated efficacy in both groups. There were significant differences between the 2 groups with respect to the age at the onset.
of UC, the estimated glomerular filtration rate on admission, underlying diseases, and concomitant therapies all correlated (all p < 0.05). Adverse events of CAP included headache (n = 2 in both groups), complications of blood reinforcement (n = 1 in the younger group), heparin allergy (n = 1 in the younger group), hypotension (n = 1 in the elderly group), and failure of blood removal (n = 2 in the elderly group). There were significant differences between the 2 groups with respect to the complications of PSL therapy (all p < 0.05).

Conclusion: Although the elderly group had longer durations of UC, a higher prevalence of underlying diseases, and a higher frequency of adverse events due to PSL therapy, CAP was effective in both groups. No serious adverse effects that required the discontinuation of CAP occurred in either group. Thus, CAP was safe and effective in both younger and elderly UC patients. CAP should be considered as a useful treatment option for UC, especially in patients with adverse events due to PSL therapy and elderly patients with underlying diseases.

Introduction: Thiopurines are the most commonly used immunosuppressive therapies in mild-to-moderate IBD. Therapeutic concentration of 6-TG is between 235–450 pmol/l × 10³ red blood cell count (RBC). The effect of body composition on 6-TG level was never studied. Furthermore, clinical data suggested a synergistic effect between thiopurine and anti-tumour necrosis factor (anti-TNF) therapy in IBD.

Aims and Methods: This is a cross-sectional study involving 96 IBD patients. Consecutive IBD patients on maintenance AZA (n = 32) and on IFX/AZA or ADA/AZA combinations (n = 32) and activity indices-based pair-matched controls on IFX or ADA monotherapy (n = 32) were prospectively enrolled. 6-TG level was measured with high performance liquid chromatography, IFX and ADA levels were assessed by ELISA method. Body composition analysis was performed with bioelectrical impedance analysis.

Results: Therapeutic concentration of 6-TG was found in 50 patients (78%), they received AZA for a mean 5.9 years. 14 patients (21.8%) had lower blood 6-TG level, they received AZA for an average of 7.5 years. The level of AZA metabolite 6-TG correlated with body weight-based AZA doses (p = 0.017) however it did not correlate with body surface area-based AZA doses (p = 0.081). With statistical analysis correlation was found with some of the investigated body composition parameters: total body water (r = 0.325, p = 0.011), intra-, extracellular water (r = 0.325 and r = 0.334, p = 0.008 and p = 0.008, respectively), scetellar muscle mass (r = 0.326, p = 0.001). However no correlation was found with body fat mass (r = -0.091, p = 0.487). 32 patients received concomitant biological therapy (14 ADA, 18 IFX). Difference was found in ADA trough levels between those on combined IFX/AZA therapy and those on ADA monotherapy (5.22 ± 5.17 mg/ml vs. 18.04 ±14.84 mg/ml, p = 0.006). In contrast, no difference was found in IFX trough levels between those on combined IFX/AZA therapy and those on IFX monotherapy (8.95 ± 10.08 mcg/ml vs. 12.13 ± 12.61 mcg/ml, p = 0.374).

Conclusion: Our study revealed that 6-TG level besides body weight-based AZA doses correlated with total body water, intra- extracellular water and scetellar muscle mass. We found a significant difference in ADA trough levels between the ADA/AZA combination group and the ADA monotherapy group. Preliminary results of our study suggest that favourable outcomes of combinations therapy may related to a synergistic effect between AZA metabolites and IFX or ADA trough levels. However the small number of the patients requires further investigations.

Disclosure: Nothing to disclose.

P0377 STRUCTURING CROHN'S DISEASE - CAN WE PREDICT NEED FOR SURGERY AT FIRST HOSPITALIZATIONS?

S Xavier1,2, T Córdia Gonçalves3,4, F.D Castro2,3,4, J.L.T.M Magalhães3,4, M.J Moreira1,2, J Cotter1,2,5

4Centro Hospitalar do Porto, Gastroenterology, Porto, Portugal
5Hospital Santa António, Gastroenterology, Porto, Portugal

Contact E-Mail Address: tiagomcg@hotmail.com

Introduction: Patients with stricturing Crohn’s disease (CD) are frequently hospitalized and a significant percentage requires surgery in the course of the disease.

Aims and Methods: We aimed to assess if there are any predictors of surgical management by the time of the first admission to hospital with obstructed bowel syndrome.

Retrospective unicentric study. Patients over 18 years old, with structuring ileal or ileocolic involvement, with at least 1 hospitalization and a minimum follow-up of 1 year were included. Excluded patients with penetrating disease, those who had their first hospitalization before anti-TNF agents became available in our center and those without appropriate records. Several clinical, analytical and radiological variables were assessed. Statistical analysis was performed using SPSS v23.0.

Results: 43 patients of which 53.5% underwent surgery to treat structuring disease. Patients had a mean age of 43.3 ±10.8 years, 53.5% were females and the median follow up time was 11.0 ±7.0 years.

Comparing patients with and without need for surgery, no significant differences were found between groups regarding age at diagnosis, presence of perianal disease, family history and smoking habits, however females were more frequently admitted to surgery (73.9% vs 30.0%, p = 0.004) as well as patients with inflammatory behavior at diagnosis. Patients with inflammatory behavior at diagnosis (65.6% vs 18.2%, p = 0.006).

At the first hospitalization, patients with need for surgery were less frequently under anti-TNF (0.0% vs 20.0%, p = 0.039), presented with longer-standing obstruction (3.0 ±15 days vs 1.0 ±15 days, p = 0.010), higher leukocytes count (12.0 ±5.3 x10³/µL vs 9.2 ±2.6 x10³/µL, p = 0.037) and admission computed tomography (CT) more frequently showed proximal small bowel dilatation (86.4% vs 40.0%, p = 0.002) and longer extent of small bowel involved (8.0 ±12.0 cm vs 5.0 ±7.0 cm, p = 0.016). Also, patients that were diagnosed by the time of the first hospitalization were more frequently submitted to surgery than those who already had a CD diagnosis (60.9% vs 39.1%, p = 0.043).

Conclusion: Females, patients with structuring behavior from diagnosis and those diagnosed in the first hospitalization were more frequently submitted to surgery. Small bowel dilatation and extent of small bowel involved in admission CT, leukocyte count and duration of obstructed bowel symptoms at the first admission were also predictors of need for surgery. Anti-TNF therapy in the first admission seems to reduce need for surgery in this group of patients.

Disclosure: Nothing to declare.

P0378 THE ROLE OF STOMA FOR COLONIC AND PERIANAL CROHN'S DISEASE IN THE BIOLOGICAL ERA

M Rocha1, J Correia-Sousa1, M Salgado1, P Lago1, C Caetano1, D Ferreira1, M Santos2, A Rocha1, J Pedroti1

Introduction: In the biological era, surgical treatment continues to play an active role in some patients with colocoleral or perianal Crohn’s disease (CD).

Aims and Methods: Epidemiological analysis, surgical indication and clinical evolution of patients with CD with colorectal and/or perianal disease undergoing surgical treatment.

Retrospective study of patients with colonic and/or perianal CD who underwent colectomy, total proctocolectomy, or diverting ileostomy /colostomy between 2000-2016 in a tertiary hospital. Demographic and clinical data were collected.

Results: 20 patients were included, 70.0% were women, mean age was 44.5 years. The disease was located in the ileum and colon in 7, solely in the colon in 11 patients and in the ileum (L1p) in 2. 13 patients had perianal disease and 18 rectal involvement. The behaviour of CD according to the Vienna classification was non-stricturing non-penetrating in 12 patients, stricturing in 5 and in penetrating 3. Prior to surgery, 15 patients were treated with combination therapy, 2 with anti-TNF (previously withdrawal of azathioprine due to adverse events). 6 patients had no medical treatment due to inaugural disease at the time of surgery. The mean duration of disease before colectomy was 9.1 years. Surgical indications were: refractoriness to medical treatment in 8 patients with luminal disease and 8 with perianal fistulizing disease, perforation in 3 and Hoggins lymphoma of the rectum in 1. 9 patients required more than 1 surgical intervention, including 4 urgent surgeries. The surgeries performed were proctocolectomy in 10 patients, total colectomy with ileostomy in 3, proctectomy with colectomy in 2, segmental colectomy with colostomy in 1 and ostomy in 4 (3 colostomy and 1 ileostomy). The mean follow-up time was 5.4 years. Postoperative evolution: high-output ileostomy in 1 patient; pelvic floor dysynergia in the patient with ileo-anal pouch; 5 patients with relapse of CD in the ileum; 2 with proctitis (1 underwent
proctectomy later); I with perianal disease and I due to adenocarcinoma in follow-up. After 1st follow-up, 9 patients were with combination therapy, 3 with biological therapy and 2 with methotrexate.

Conclusion: In this study, 95% remained with stoma. More than half of the patients maintain/restart biological treatment.

Disclosure: Nothing to disclose.

P0379 ENTERIC RESECTION IN CROHN’S DISEASE - IS THERE A RELATIONSHIP BETWEEN THE TIMING OF IMMUNOSUPPRESSION ONSET AND THE EXTENSION OF THE RESECTED SMALL BOWEL?

P Costa-Moreira, P Andrade, S Lopes, A.L Santos, C.R Nunes A. Macedo Centro Hospitalar de São João, Gastroenterology, Porto, Portugal

Contact E-Mail Address: pedromoreira.med@gmail.com

Introduction: Intestinal function is closely related to its length. An individualized approach regarding the need for resection of each affected segment of the bowel should be applied to the patient with Crohn’s disease (CD) requiring surgery. Several studies have been evaluating the relationship between the date of onset of anti-tumor necrosis factor (anti-TNF) agents or immunomodulators and the need of surgical procedures in CD. However, it is still unclear if the timing of the immunosuppression onset has impact in the length of the resected small bowel.

Aims and Methods: We propose to evaluate the relationship between the early treatment of CD patients with anti-TNF agents or immunomodulators with the extension of the resected small bowel. We perform a retrospective data analysis of a sample of cases with CD submitted to surgery. For each case, the date of diagnosis, immunomodulators or anti-TNF onset, and surgery was recorded. The extension of the resected small bowel was based on the anatopathological report.

Results: A total of 314 cases diagnosed between 1975 and 2017 (172 men (50.7%), mean age at diagnosis 28.9 ± 12.8 years) were evaluated. Multiple surgeries were performed in 20% (n = 63) of the cases. The most frequently performed surgery was the right ileocolic resection (77.3%, n = 222 patients).

The median time between diagnosis and the first surgery was 31 months (IQR 5–83 months). On average, the patients underwent resection of 23.6 ± 18.4 cm of the small bowel. Prior to the first surgery, 46.7% (n = 148) of the patients were treated with an immunomodulator (median time of therapy 16 months, IQR 3–42 months) and 21.8% (n = 69) were treated with an anti-TNF agent (median time of therapy 38 months, IQR 7–100 months). Neither immunomodulatory therapy (mean 23.2 ± 16.5 cm vs. 24.3 ± 20.4 cm, p = 0.67) nor anti-TNF therapy (mean 23.7 ± 19.5 cm vs. 24 cm, p = 0.61) was associated with lower extension of resected small bowel. No correlation was found between the time elapsed since diagnosis and introduction of the immunomodulator (r = 0.07, p = 0.43) or anti-TNF agent (r = 0.06, p = 0.53) and the extension of resected small bowel. Also, there was no correlation between the time elapsed between the introduction of immunomodulator (r = 0.06, p = 0.47) or anti-TNF agent (r = 0.08, p = 0.53) and time to surgery with the extension of resected small bowel.

Conclusion: In this group of patients, we found that the timing of introduction of immunomodulator or anti-TNF therapy did not influence the extent of the resected bowel.

Disclosure: Nothing to disclose.

P0380 HIGHER BMI BUT NOT SYSTEMIC IMMUNE SUPPRESSION INCREASES THE RISK OF SHORT-TERM POSTOPERATIVE COMPLICATIONS IN CROHN’S DISEASE PATIENTS

D Podmanicky1, V Bala2, M Krizko2, Z Zelinkova2
1St Michaels Hospital, Department of Surgery, Bratislava, Slovakia
2St Michaels Hospital, Department of Gastroenterology, Bratislava, Slovakia

Contact E-Mail Address: dusan.podmanicky@nsms.sk

Introduction: Several studies have focused at the risk factors of postoperative complications in Crohn’s disease (CD) patients with no conclusive results. Thus far, it is unclear whether immune suppression should be adjusted in a CD patient awaiting surgery for CD complications.

Aims and Methods: The aim of this study was to determine the risk factors associated with the postoperative complications in CD patients operated for luminal disease complications.

All consecutive CD patients operated on in 1 tertiary center between January 2015 and September 2017 were included. Complications within 30 days following surgery were categorized according to Clavien-Dindo classification. Patients’ demographics, nutritional status, disease localization and behavior, type of medical therapy, previous surgical interventions, type of surgical approach and duration of surgical intervention were noted. The association of postoperative complications with these factors was analyzed.

Results: In total, 91 procedures were performed in 86 CD patients (47.3% males; mean age 38 years, range 17–71; 56 pts (61.5%) with ileo-colonic disease, 11 pts (12.1%) with small bowel and 21 pts (23.1%) large bowel localization; 62 (68.1%) with stricturing disease). Based on body mass index, 23 (25.3%) patients were underweight, 42 (46.2%) had normal weight and 21 (23.1%) were overweight. Minority of patients had stenosis (16 pts (17.6%); 36 pts (39.6%) were using azathioprine; 33 (36.3%) anti-TNF; 7 (7.7%) vedolizumab and 1 patient was using trial medication.

The procedure was elective in 60.4% and one-third had repetitive surgery. Median duration of the procedure was 150 minutes (range 30–335) and median hospital stay was 6 days (range 3–32). 51 pts (56%) had simple resection, 24 (26.4%) had multiple resections, in 16 cases an ostomy was created. Laparoscopic approach was used in 44 cases (48.4%; 8 pts had single port laparoscopic procedure). 46 pts (50.5%) had laparotomy. There were 10 complications (11%) out of which 5 (5.5%) major complications (Clavien-Dindo IIIb and above). There was a significant difference in BMI between patients with major complications compared with patients without complications in all the groups with major complications vs. group without complications (p = 0.035). None of the other factors were associated with unfavorable postoperative outcomes.

Conclusion: Overweight represents a risk factor for postoperative complications in CD patients operated for luminal disease complications. Immune suppressive therapy, including systemic corticosteroids and anti-TNF biologics does not seem to confer an increased risk for surgical complications.

Disclosure: Nothing to disclose.

P0381 USING PATIENTS’ PREFERENCE IN RANDOMIZED CONTROLLED TRIALS

K Wasmann1, P Wijman1, S van Dieren1, W.A.Bemelman1, C.J Buskens1
1Academ. Medisch Centrum Amsterdam, Department of Surgery, Amsterdam, Netherlands
2Sparnae Gasthuis, Department of Internal Medicine, Hoofddorp, Netherlands
3Academ. Medisch Centrum Amsterdam, Department of Epidemiology, Amsterdam, Netherlands

Contact E-Mail Address: k.a.wasmann@amc.nl

Introduction: Randomized controlled trials (RCT) are the gold standard of assessment of efficacy in clinical medicine. However, many eligible trial participants have a preference for 1 of the intervention of the RCT, and therefore may decline randomization. Consequently, this could limit the extrapolation of the results to the clinical population (i.e. reduce external validity by randomization bias).

Recently, a preference for one randomization arm was encountered. Intervention may experience resentful demoralization, which may lead to worse outcomes (i.e. reduce internal validity by preference bias). Especially studies with a substation difference in interventions (e.g. surgery vs. medication), and studies with a subjective primary outcome (e.g. quality of life), are prone for randomization and preference bias.

The aim of this study was to determine whether preferences affect external and internal validity in trials.

Aims and Methods: A systematic review with meta-analyses was performed. 2 reviewers independently searched in MEDLINE, EMBASE, PsychINFO, and the Cochrane library for RCTs with a preference-arm published between 2005 and 2018. The trials that reported on allocation of patients to random or preference cohorts using the same inclusion criteria and protocol were included. We extracted data on study design, measurement of preference, recruitment, attrition, cross-over, and primary outcome at baseline and end of follow-up.

Results: In total 117 out of 3734 identified articles met screening criteria and 35 were eligible (to compare baseline and primary outcome difference between the placebo and preference cohort, 32 and 20 articles were included, resp.) Acceptance of randomization in all 35 trials varied from 1% to 81% and was lower than 50% in 23 of 35 studies. Higher education level, female, older age, race, and prior experience with 1 treatment arm were baseline characteristics of participants declining randomization. The primary outcome of the trials between randomized and preference groups was comparable, the difference in effect of the experimental intervention was 0.093 (95% CI –0.364–0.178), p = 0.502. After comparing only the 7 trials that adjusted for baseline difference the effect was even smaller, 0.026 (95%CI –0.211–0.263), p = 0.832.

Conclusion: Treatment preference led to a substantial proportion of a specific patient group refusing randomization, while it did not affect the primary outcome. Therefore, patients preference trials could increase external validity without compromising the internal validity compared to randomized controlled trials.

Disclosure: Nothing to disclose.

P0382 EARLY CLOSURE OF ILEAL POUCH-ANAL ANASTOMOTIC LEAKAGE PRESERVES POUCH FUNCTION; A PROSPECTIVE COHORT STUDY

K Wasmann1, M Rejinjies1, M Stellingwerf1, C.Y Ponsiesen2, C.J Buskens3, R Hompes1, P Tanis4, W.A Bemelman4
1Academ. Medisch Centrum Amsterdam, Department of Surgery and Gastroenterology, Amsterdam, Netherlands
2Academ. Medisch Centrum Amsterdam, Amsterdam, Netherlands
3Academ. Medisch Centrum Amsterdam, Amsterdam, Netherlands
4Academ. Medical Center, Surgery, Amsterdam, Netherlands

Contact E-Mail Address: k.a.wasmann@amc.nl

Introduction: In case of ileal pouch-anal anastomotic (IPAA) leakage, Endosponge®-assisted early surgical closure prevents chronic presacral abscesses compared to conventional treatment (defunctioning ileostomy and passive drainage). It was hypothesised that early closure would also improve long-term pouch function. The aim of this study was to compare pouch function and failure after early closure to conventional management of anastomotic leakage and to control IPAA patients without anastomotic leakage.

Disclosure: Nothing to disclose.
Aims and Methods: In this prospective cohort study, all consecutive patients who underwent colectomy for UC between 2002 and 2017, were sent a validated stool PCR questionnaire. Early surgical closure was defined as ≥3 days of hospitalization induced by acute diarrhea. The prevalence of children with autism spectrum disorders (ASD) is increasing worldwide (1). The cause of ASD is poorly understood and involves interactions of different genetic and environmental factors where gut microbiota could have a significant impact. The aims of the study were to evaluate fecal microbiota transplantation (FMT) effectiveness in children with ASD in treating autism spectrum disorders and gastrointestinal (GI) symptoms.

Aims and Methods: We performed FMT in 5 boys (5–8 yrs, every month, 3 times for each patient) with ASD and mild GI symptoms. The donor was the same 7 yrs. old healthy, unrelated girl. Her feces were infused into the cecum during colonoscopy. The patient’s gut before FMT was prepared with polyethylene glycol 4000 (Fortrans). Symptoms were checked every week after FMT with patient global impression score (PGI-R; the symptoms were rated on a scale of 1–7, where 1 = much worse, 7 = much better compared to baseline) (2) for ASD and gastrointestinal symptom rating scale (GSRS; 1 represents absence of troublesome symptoms and 7 represents very troublesome symptoms) (3).

Results: We filled GSRS and PGI-R scores by asking parents about their child’s health during phone call or when the patient came to the hospital for FMT. The total GSRS and PGI-R scores improved in all (1–5) patients after FMT (Table 1). The best improvement was seen after 2 wk. post FMT, less before second and third FMT. The FMT treatments were generally well-tolerated, without adverse effects.

Conclusion: FMT has positive effect on GI and autism spectrum disorders symptoms.

Disclosure: Nothing to disclose.

Conclusion: Colitis mimicking ulcerative colitis is 1 of irAEs induced nivolumab. Our diagnostic criteria, which include apoptosis of colonic epithelial cells, may be appropriate in consideration of mucosal damages and subsequent clinical course.

Disclosure: Nothing to disclose.
Results: Overall, 29 (30%) of 96 samples were positive for pathogen at stool PCR. The most frequently detected virus was norovirus (28.2%) and adenovirus was detected in 1 sample, respectively. The positive rate for bacteria was 48.3% (28/58). C. perfringens was the most frequently detected, followed by campylobacter spp., Caldificle toxin B. The rate of antibiotics change, anti-diarrhoeal agent or probiotics change, additional endoscopy and image study (CT) were significantly higher in stool PCR positive group (p = 0.007, p < 0.01, p = 0.018 and p = 0.027, respectively).

There were no significant differences between groups in terms of antibiotics use and hospitalization. However, hospital of day decreased significantly in stool PCR positive group (p = 0.032).

On multivariate analysis, stool PCR positive was associated with increased rates of history of diabetes mellitus type 2, fluid therapy and anti-diarrheal agent use (HR, 3.857; 95% CI 2.381–9.238; p = 0.001) / HR 2.949; 95% CI 1.184–7.303; p = 0.020 / HR 2.945; 95% CI 1.522–5.699; p = 0.001).

Conclusion: With stool PCR positive, antibiotics changes and drug modification were associated shortening of hospitalization period, espacially in patients with diabetes.

Disclosure: Nothing to disclose

Introduction: Fecal microbial transplantation (FMT) has been established as an effective and safe therapy for recurrent Clostridium difficile infection (CDI), with cure rates of 85–95% [1]. In Israel, FMT for the treatment of recurrent CDI, has been performed for the past 3 years. It is widely accepted that at which FMT is performed in ambulatory as well as in hospitalized patients using multiple methods including colonoscopy, gastroscopy, and capsules [2–3].

Aims and Methods: We evaluated and described the efficacy and safety of FMT for CDI patients in a national retrospective cohort of the 5 medical centers performing FMT in Israel. All patients who received FMT for recurrent (recurrence within 8 weeks of the previous treatment), refractory (ongoing diarrhea despite antimicrobial treatment) or severe CDI (WBC > 15,000 c/μL ± CR > 1.5 times the premorbid level) from 2013 through 2017 were included.

Stool donors were screened according to the Israeli Ministry of Health guidelines. Fecal filtrates were locally prepared and stored frozen in −80°C. Clinical and laboratory data of patients were collected from patients’ medical files in which indications for FMT, risk factors and outcomes at 1 week, 2 and 6 months post FMT are routinely recorded.

Results: A total of 111 FMTs for CDI were performed: 45% via the lower GI route (LGI) through a colonoscopy, 22% via gastroscopy or feeding tube (upper GI - UGI), and 33% via oral capsules. A summary of patients’ characteristics, risk factors for CDI, indications and outcomes is depicted in Table 1.

Recurrent CDI was the leading indication for FMT in 74% of the patients while refractory and severe CDI were treated in 21% and 18% patients, respectively.

Contact E-Mail Address: sharon.greenberg@gmail.com
Overall success rate was 87.4% (97 patients), with no significant difference between administration routes. Patients who achieved cure, were younger (age 63±22 compared with 73±12, p < 0.05), were less often defined as severe CDI, and were more likely to be treated as outpatients. Patients who were younger than 60 years old (n = 35), were mostly outpatients, compared to the elderly group, (86% vs. 63%, respectively, p < 0.05) and underwent FMT at a much later time from first disease episode (mean time from 1st CDI episode 27% vs. 102±112 days, p < 0.001). 11 patients died during the follow-up, none was attributed to the FMT procedure. No FMT related infections were recorded.

Disclosure: Nothing to disclose.

Introduction: Clostridium difficile infection (CDI) has emerged as a major health-care-associated infection, because of the changing molecular epidemiology of the C. difficile, and the ageing of the population, without neglecting frequent exposure to broad-spectrum antibiotics and other predisposing medications, the prevalence of comorbidities, and the risk of hospitalization. In the last decade, analyses of hospitalization records and data on multiple causes of death demonstrated an important and constant increase in CDI rates. Aims and Methods: To evaluate the impact of CDI on hospitalization in Veneto Region (North-East Italy, approximately 4,900,000 inhabitants), a retrospective analysis was carried out from a population-based archives represented by hospital discharge records (HDR) according to the ICD9-CM. All discharges from 1 January 2007 to 31 December 2016 of Veneto population with a code for CDI (008.45) as principal or secondary diagnosis were extracted from the regional anonymous archive of discharge records. The Standardized Hospitalisation Rate (SHR) and in-hospital Mortality Rate (SMR) were calculated per 5-year age group. Results: 7,557 discharges with CDI were tracked in the study period and 88% of these hospitalizations involved subjects aged over 65 years, with CDI diagnosis as the primary in over 1-third of cases and an overall lenght of stay (LOS) of 25.6±22.7 days. Hospitalization distribution by gender showed a prevalence of females (63.7%) characterized by a higher mean age (80.2±14.6 vs. 75.6±16.4 yrs; p < 0.001). The SHR was 15.25 and SMR 1.72 both increased steeply and constantly in the analyzed period, and from the comparison of first and last year of the period emerged a rise of SHR (Chi square for trend: 141.702; p < 0.001) from 10.6 to 24.5 and also of SMR (Chi square for trend: 45.381; p < 0.001) from 0.6 to 3.7 per 100,000 inhabitants. The rate of CDI diagnoses per 10,000 annual admissions increased steeply with age, and reached a peak of 222.4 every 100,000 discharges among the very elderly (≥ 85 years). In the frame of over 65 years patients the age class distribution showed a higher risk in 75–84 (OR: 1.62; CI95%: 1.35–1.92; p < 0.001) and an almost double in >85 years (OR: 2.1; CI95%: 1.56–2.74; p < 0.001) respect to 65–74 age class. Conclusion: In the observation period SHR for CDI was almost doubled and SMR even increased 6-fold in 2016 respect to 2007. What emerged confirms the literature’s data about the time course of CDI infections, with an increase in their frequency, as well as in their severity and in the additional days of hospitalization. These dramatic scenario imposing the adoption of adequate containment measures to deal with a new epidemic phenomenon, mainly through policies to optimize antibiotic therapy both in the intra- and extra-hospital environment.

Introduction: Clostridium difficile infection, especially in its severe clinical picture, is a risk factor for bloodstream infections (BSI). A considerable body of evidence shows that fecal microbiota transplantation (FMT) is more effective than standard antibiotic regimens (metronidazole or vancomycin) in treating recurrent CDI, although its efficacy in reducing CDI-related BSI has not yet been demonstrated.

Aims and Methods: The aim of this study is to assess the rate of BSI in a cohort of patients with CDI treated with FMT or with standard antibiotic therapy. This is a single-centre, retrospective cohort study of patients with CDI treated with FMT either with standard antibiotic regimens (metronidazole or vancomycin) or fidaxomicin. The date of first fecal inoculation and the starting date of antibiotic treatment were considered as time 0 for the analysis.

Results: At November 2017, 282 subjects (F = 91, M = 171, mean age 74 years) were analysed for this study. Of them, 101 patients (36%) were treated with FMT from healthy donor and 181 (64%) received antibiotic therapy for CDI. No differences were found on demographic and clinical characteristics of the 2 study groups.

47 patients developed a BSI after FMT or standard antibiotic therapy. Compared to those who received antibiotic treatment for CDI, patients in the FMT group had a significantly lower risk of overall BSI (21.3% versus 8.9%; p = 0.008), fungal BSI (6.6% versus 1%; p = 0.036), polymicrobial BSI (6.1% versus 1%; p = 0.016). Subjects in the FMT group experienced also a significantly shorter length of hospitalization compared to those in the antibiotic group (13.4 days versus 29.8 days on average; p < 0.001) and a reduced death risk at 60 days (7.7% versus 1%; p = 0.015). Adverse events were similar between the 2 groups.

Conclusion: In our cohort, subjects with recurrent CDI treated with FMT experienced a significantly lower incidence of bloodstream infections, a shorter length...
of hospitalization and a reduced 60-day risk of death compared to those who received antibiotics. We can argue that a rapid restoration of healthy microbiota in people with CDI treated with FMT could explain the present results. Should these preliminary results be confirmed by prospective, randomized trials, the reduction of BSI in patients with recurrent CDI may be considered an additional relevant benefit of FMT.

Disclosure: Nothing to disclose

Aims and Methods: We aimed to study the profile and predictors of difficult to treat (DTT-TB) inclusive of MDR-TB patients of all the confirmed cases of abdominal TB. Clinical, laboratory and radiological data of abdominal TB (n = 83) were analysed from 2012-2017. Disease rates of previous years (2000-11) were compared. DTT-TB was defined as 1 of the following: 1) prolonged (>9months) WHO category-1 antibacterial therapy (ATT), 2) MDR-TB (failed WHO category-2± category-1 ATT or proven on GeneXpert) requiring second line therapy. DTT-TB was compared with standard ATT (WHO category 1 or 2 responsive of ≤9months duration of therapy) cases.

Results: Of all abdominal TB, MDR-TB was diagnosed in 3 of 38 (8%); 2000-11 and 13 of 83 (16%; 2012-17). An additional 7 of 83 children (2012-17) had prolonged category-1 ATT finally constituting 20 (24%) as DTT-TB. Table 1 shows the comparison of DTT-TB and standard therapy. Overall confirmation of diagnosis (n = 83) was 56 (67%) by microbiology or histology (caseating granuloma), the rest by discriminatory radiological ± laboratory features. Younger age, higher microbiological yield, presence of extra-abdominal, thoracic, and abdominal lymph node involvement and paucity of luminal involvement were significant in DTT-TB than standard therapy. In the DTT-TB group, prolonged ATT (n = 7) was administered for 17.7±5.1 months and MDR-TB (n = 13) for 18±6.9 months. At the end of 18 months, 3 of 13 (23%) MDR-TB were non-responsive to various second line agents and were labeled extended drug resistant TB.

Conclusion: An alarming rise of overall abdominal TB, MDR-TB and extended drug resistant TB is currently encountered in developing countries. MDR-TB is multibacillary and presents as disseminated disease affecting younger age groups.

Contact E-Mail Address: sogata@ndmc.ac.jp

Introduction: Diagnosing human intestinal spirochetosis (HIS), a colorectal infectious disease caused by *B. aalborgi*, is difficult. The disease is classified as a phase-1 intestinal infection. In most cases, patients have no symptoms or present with non-specific gastrointestinal symptoms. The disease is confirmed by biopsy and detection of *B. aalborgi* using PCR in stool or sigmoidoscopic specimens in the pathology department at a single hospital.

Results: Among the 140 individuals examined (M:F=86:54; 20–94 yrs; median 64 yrs) during the period, 10 HIS-HE cases (7.1%; M:5; 5:34–75 yrs; median 57 yrs) were diagnosed, while HE pathology found eight HIS-HE cases (so-called ‘colon’ cases: thick and distinct; 5.7%) and 2 possible cases. All 8 HIS-HE cases matched HIS-HE cases. However, the 2 possible HIS-HE cases were denied by IHC, while another 2 of the HIS-HE cases were overlooked by HE. In the HIS-HE cases confirmed by HIS-IHC at the time, 4 HIS-HE cases have received endoscopy as follow-up for polys, 1 for ulcerative collitis, 2 for fecal occult blood, and 1 for watery diarrhea.

Conclusion: The hallmark of HIS can be observed histologically, and an initial IHC application might find more HIS cases in routine practice.

Introduction: The recommended strategy of the use of colonoscopy after preparation by oral lavage at patients with low-intestinal bleeding identifies the source of bleeding in 23%–40%. The frequency of these sources are significantly different. Identifying the source of bleeding involves the wrong tactics and volume of treatment. What is more important at low intestinal bleeding: total colonoscopy or search for the true source of the bleeding?

Aims and Methods: Compare the structure identified during the colonoscopy sources of bleeding in patients presenting at patients previously oral lavage versus patients who performed urgent colonoscopy without bowel preparation.

A randomized cohort study. Included 252 patients admitted from the signs of intestinal hemorrhage in 2006–2015. 118 men, women 134. The average age of the patients was 60.1±15.7 years. In Hosp No 29 colonoscopy was performed at admission without prior preparation of the colon, the patient in Hosp No 1 performed lavage or enema preparation prior to colonoscopy within 24–48 hours of hospital stay.

Results: Significant differences in the structure of intestinal bleeding sources (p=2.3–4.500000, p=0.03390) are revealed. In patients without bowel preparation the most frequently detected were bleeding diverticula and cancers -17%, ulcerative colitis -10%, intestinal bleeding -16%, upper bleeding -16%. In preliminary bowel preparation the most likely cases of bleeding detected were cancers -7%, ulcerative colitis -15%, angiodysplasia -13%. The number of endoscopic findings in bowel preparation was 1.5 times higher against emergency colonoscopy without bowel preparation. The number and structure of the observed changes were significantly different between both groups, and depending on the sex of patients (p=2.3–112.4894, p<0.0000). There were no complications in both groups. Another aspect of the question consists of the need to use hemostasis methods. In our observations at active bleedings we used hemostasis methods in only 3 patients (1.2%). It not in favor of an early colonoscopy without preliminary preparation of a colon. These data differ from other authors who use a hemostasis in 25% or 40%. Apparently, tactical decisions in favor of using a colonoscopy without bowel preparation should be based on experience of clinical and regional features of nosological focal bleeding in patients with presumptive diverticular hemorrhage.

Conclusion: Performing a colonoscopy at an altitude of bleeding without colon preparation is safe, but significantly alters the structure of the true sources (causes) of bleeding. Colonoscopy after preliminary bowel preparation has significantly higher diagnostic capabilities, which complicates the identification of the true source of bleeding. The choice in favor of a colonoscopy without intestinal preparation should be individual.

Introduction: The number of nonagenarians hospitalized for various reasons including acute lower gastrointestinal bleeding (ALGIB) is increasing worldwide.

Aims and Methods: Our aim was to evaluate whether clinical characteristics and outcomes in nonagenarians with ALGIB differ from younger patients.

Data from all nonagenarians with ALGIB hospitalized in our hospital over a 76-year period were compared with those <90 years old. Hemodynamic resuscitation, management of antithrombotic agents, early colonoscopy following bowel cleansing, capsule enteroscopy and endoscopic hemostasis when needed were the main steps in the management of patients with ALGIB. In cases of hemodynamic instability, emergent CTA was performed with embolization when appropriate.

Results: Data of 32 nonagenarians (91.8±2.1, 90–99) were compared with that of 496 patients <90years (68.8±14.1, 17–89). Nonagenarians were more commonly female (24/32 vs 232/496, p=0.003) with higher serum creatinine levels (1.4±0.8 vs 1.0 ±0.7, p=0.046) and higher rate of coexisting diseases (32/32 vs 430/496, p=0.023), mainly cardiovascular (23/32 vs 241/496, p=0.017). Proper bowel preparation (25/32 vs 438/496) and endoscopic examination (29/32 vs 417/496) did not differ. The cause of bleeding was not different (mainly diverticula, ischemic colitis and neoplasia in 8, 9 and 4/32 nonagenarians respectively). No significant difference was observed between the 2 groups regarding transfusions (1.1±1.8 vs 0.9±1.9, p=0.524), hospitalization days (5.0±4.2 vs 4.3±3.2, p=0.150), recurrence of bleeding (1.3±36/496, p=0.72), urgent surgical hemostasis (0.3±6/496, p=0.69) and mortality (2.3±411/496, p=0.19).

Conclusion: Despite the age and higher prevalence of concomitant diseases, nonagenarians had a worse bleeding outcome.

Disclosure: Nothing to disclose.

**P0398 MANAGEMENT OF ANTITHROMBOTIC AGENTS IN PATIENTS WITH PRESUMPTIVE DIVERTICULAR HEMORRHAGE**

Introduction: It has been reported 5–15% of definite diverticular hemorrhage patients experience re-bleeding within 30 days regardless of status of re-initiation of antithrombotic agents. About 65% of diverticular hemorrhage patients are diagnosed as presumptive hemorrhage.

Aims and Methods: This study aimed to elucidate risk factors predicting re-bleeding in patients with presumptive diverticular hemorrhage. A total of 231 patients with presumptive diverticular hemorrhage from January 2004 to September 2017 were included retrospectively. The primary outcome was post-endoscopy re-bleeding among patients with presumptive diverticular hemorrhage. Age, sex, past medical history, laboratory results, colonoscopy procedure length, and site of bleeding were assessed as well as use of antithrombotic agents. Rebleeding was considered in patients with and without re-bleeding. In addition, among patients with presumptive diverticular hemorrhage using antithrombotic agents, we examined relationship between re-bleeding and when they restart their agents.

Result: Among the 231 patients receiving antithrombotic agents. Duration from colonoscopy to re-bleeding in patients taking antithrombotic agents and those not taking was 1.70 and 1.92 days, respectively (p=0.23). In addition, 17 of the 23 re-bleeding patients under antithrombotic agents had their antithrombotic agents re-initiated after the index
re-bleeding, with none of them experiencing another re-bleeding during the follow-up.

Conclusion: Use of antiatherosclerotic agents was not associated with re-bleeding in patients with presumptive diverticular hemorrhage after colonoscopy, potentially indicating the safety of reinitiating antiatherosclerotic agents.

**P0399** **CUMULATIVE LEVELS OF FEACAL HEMOGLOBIN IN CONSECUTIVE ROUNDS OF FIT NEGATIVE PARTICIPANTS FOR IMPROVING COLORECTAL CANCER SCREENING MANAGEMENT**

**Aims and Methods:** Our hypothesis is that the cumulative concentration of fHb in consecutive rounds might be useful to detect those individuals with high risk of neoplasia undergoing to colonoscopy. However excretion of haemoglobin to faeces (fHb) is intermittent and can be due to difference causes other than neoplasia. Moreover, it has been shown that FIT pre analytics have sources of bias and the concentration of fHb is related with age and gender. For instance, an individual may present a positive result followed by a negative result or vice versa only in a few days.

**Results:** A multivariate logistic regression identified gender (men: odds ratio [OR], 1.70; 95% confidence interval [CI], 1.39–2.12) and mean fHb concentration of the first 2 rounds (ρ < 4 μg/g; g–4 μg/g; > 4 μg/g) as independent predictive factors for CRC. Combining these factors, different risk categories have been established. A 6.59-fold (95% CI, 3.80–11.42) higher risk of CRC was found between the 2 extremes categories (see table). The positive predictive value for CRC ranged from 8.8% to 39.8%. Interestingly, negative predictive values for CRC, ranged from 93.1% to 98.5%.

**Conclusion:** Cumulative fHb concentration together with gender in FIT negative participants could be a useful tool to assess the presence or absence of CRC in subsequent screening rounds and can help in the design of strategies and the management of the programmes to enhance their efficiency.

---

**Disclosure:** Nothing to disclose.
increase did not reach statistical significance (35.64% vs 28.5%, p = 0.09).

Location of CRC in the 3 different groups is depicted in the table. Synchronous polyps were more commonly found in the right colon during G3 compared to G2 and G1 (G3 = 40.76% vs G2 = 17.12% vs G1 = 23.14%, p < 0.0001). Statistical significance remained even when analyzed separately for sex (females-right colon polyps G3 = 35.94% vs G2 = 2.7% vs G1 = 8.7%, p < 0.0001 and males right colon polyps G3 = 42.86% vs G2 = 24.32% vs G1 = 32%, p = 0.019).

Conclusion: Right colon CRCs as well as synchronous right colon polyps are significantly more frequently diagnosed in a single endoscopic center during the last 15 years. This may be due to better colon preparation, use of high definition endoscopes or increased awareness of right colon cancers by gastroenterologists.

Introduction: Limited data are available regarding the association between age at menarche and the risk of colorectal adenoma. Therefore, we aimed to evaluate the relationship between reproductive factors including age at menarche and the risk of colorectal adenoma.

Aims and Methods: A cross-sectional study was performed on asymptomatic female subjects who underwent colonoscopy between 2010 and 2014 as part of a comprehensive health screening program in Korea. The association between reproductive factors including age at menarche and the presence of adenomas was assessed using multivariate logistic regression analysis.

Results: Among 32,620 asymptomatic female subjects, the proportion of patients with menarche at 10–11, 12–13, 14–15, 16–17, and 18–19 years of age was 4.1%, 31.7%, 45.4%, 14.9%, and 4.0%, respectively. Age at menarche was not significantly associated with the risk of any adenoma (adjusted odds ratio [AOR], 0.99; 95% confidence interval [CI], 0.97 to 1.02; p = 0.500) and advanced adenoma (AOR, 0.98; 95% CI, 0.91 to 1.04; p = 0.468) after adjusting for confounding factors. Age at menarche was not significantly associated with the risk of adenoma even among the similar age group. In addition, parity, use of female hormones, and menopause were not associated with the risk of adenoma.

Conclusion: Age at menarche, parity, use of female hormones, and menopause were not significantly associated with the risk of colorectal adenoma. Our findings indicate that reproductive factors including age at menarche do not affect the development of colorectal adenoma.

P0403 METABOLIC FACTORS, LIFESTYLE HABITS AND AGING ARE ASSOCIATED WITH DEVELOPMENT OF COLORECTAL NEOPLASIA IN JAPAN

N Inoue, K Kashiwagi, T Yoshida, Y Sugino, Y Iwao
Keio University School of Medicine, Center For Preventive Medicine, Tokyo, Japan

Contact E-Mail Address: nagamu@z6.keio.jp

Introduction: For the past decades, the incidence and mortality rate of colorectal cancer (CRC) has been increased in Japan and CRC is the third leading cause of cancer death in Japan. This may reflect economic development and concomitant shifts from traditional lifestyle towards a westernized lifestyle. The association of metabolic syndrome (MetS) and CRC has been reported in several studies, however, individual factors contributing to CRC occurrence have been obscure, especially in Japan.

Aims and Methods: In the present study, we investigated the risk factors such as metabolic and lifestyle factors for the occurrence of colorectal neoplasia (CRN; adenomatous polyp ≥ 5 mm in size and cancer) and advanced neoplasia (AN; advanced adenoma and cancer, ref.) by using comprehensive health checkup data. We conducted a retrospective analysis in clinical practice at a single center. Among 10138 subjects who took comprehensive health checkup at our hospital between in August 2012 and December 2016, 2769 subjects who also underwent screening colonoscopy were enrolled. A diagnosis of MetS was made by Metabolic Syndrome Diagnostic Criteria Exploratory Committee in Japan. Demographic characteristics, anthropometric measurements, visceral fat area (VFA) measured at the umbilical level by CT, hematological metabolic parameters, degree of liver fat evaluated by ultrasoundography, and current smoking and drinking habits were assessed. Association between variables and CRN or AN was evaluated by univariate analysis using t-test, X2 test, Mann-Whitney test, and then by multivariate analysis using multiple logistic regression model. A p value < 0.05 was considered statistically significant.

Results: Of 2769 subjects analyzed, 327 subjects had CRN (11.8%) and 99 had AN (3.3%). 676 subjects were diagnosed as MetS (24.4%) and presence of MetS was significantly associated with CRN and AN (p = 0.000, 0.004). Univariate analysis identified significant association of CRN with sex, age, body mass index (BMI), VFA, systolic and diastolic blood pressure (SBP/DBP), low-density lipoprotein (LDL)-cholesterol, triglycerides (TG), fasting plasma glucose (FBG), hemoglobin A1c (HbA1c), fatty liver, smoking habits, drinking habits and ≥ 10 kg weight gain compared with the body weight at the age of 20. Logistic regression analysis revealed that age, BMI, SBP, LDL TG, current smoking and drinking habits were independent factors associated with CRN (Table). Moreover, age, LDL TG and current smoking were recognized as independent factors associated with AN.

Conclusion: The present study demonstrated that metabolic factors, especially dyslipidemia, age, and current smoking were risk factors for development of colorectal neoplasia in Japan.

P0404 COMPARISON OF COLORECTAL POLYS WITH SIZE BETWEEN 6 AND 20 MILLIMETERS IN YOUNGER AND OLDER INDIVIDUALS

C.-W Chen, W.-R Lin, C.-T Chiu
Lin Kou Chang Gang Memorial Hospital, Department of Gastroenterology and Hepatology, Taoyuan, Taiwan

Contact E-Mail Address: 8902088@adm.cghm.org.tw

Introduction: According to the recommendation by the U.S. Multi-Society Task Force on Colorectal Cancer, colonoscopy screening for colorectal neoplasm should be performed for individuals for 50 years old and over. Over the last decades, the incidence and mortality of colorectal cancers (CRCs) in individuals who are 50 or more years old have been decreasing. In contrast, the incidence of CRCs in individuals less than 50 years old has been increasing. Several studies demonstrated that CRCs in older individuals have a different biology compared to younger individuals. However, the data on the characteristics of colon polyp in individuals aged <50 years is limited.

Aims and Methods: The aim of this study was to investigate the characteristics of colorectal neoplasm in individuals aged <50 years and to compared them to those of individuals ≥50 years old. From Jan 1, 2015, to Jan 31, 2017, patients
who underwent snare polypectomy with polyp’s size between 6 and 20 millimeters (mm) were enrolled in a tertiary medical center of northern Taiwan. The demography of patients and the polyp characteristics, including pathological findings, size, morphology and location, were recorded. Descriptive statistics and frequency distributions were calculated. The data were analyzed by using either the Mann-Whitney U test for continuous variables or chi-square test for categorical variables. Statistical significance was defined as p < 0.05.

Results: A total of 1925 polyps in 1424 patients were included in this study. There were 323 polyps in 264 patients < 50 years old (younger group) and 1602 polyps in 1160 patients ≥ 50 years old (older group). In the younger group, 193 patients were male (69.3 %), with a median age of 44 years old (range: 19-49 years old). The median size of polyps was 10 mm (range: 6-20 mm) in the younger group. Most polyps in the younger group were in the distal colon (65.2 %) and pedunculated shape (83.6 %). Furthermore, the ratio of the prevalence of the distal colon polyp and pedunculated polyp was significantly higher in the younger group (62.8 % vs. 55.2 %, p = 0.011; 16.4 % vs 12.3 %, p = 0.045) respectively. In the polyp pathological findings, there were 57 (17.1 %) polyps with high-grade dysplasia, 20 (6.2 %) sessile serrated adenomas, 158 (48.9 %) tubular adenoma, 52 (16.1 %) tubulovillous adenoma, 6 (1.9 %) villous adenoma and 2 (0.6 %) high-grade dysplasia in the younger group. In the high-risk polyp subgroup, the prevalence of sessile serrated adenoma and ≥ 10 mm serrated adenoma was significantly higher in the younger group compared to the older group (6.2 % vs 2.7 %, p = 0.002; 3.4 % vs. 1.4 %, p = 0.042) respectively. The prevalence of polyps with high-grade dysplasia was significantly higher in the older group (3.8 % vs 0.6 %, p = 0.014). There was no significant difference between both groups in terms of polyps with size ≥ 10 mm and polyps with villous component.

Conclusion: In the polyps with size between 6 and 20 mm, the prevalence of left sided polyps and pedunculated polyp is significantly higher in patients < 50 years old. In the high-risk polyp subgroup, the prevalence of sessile serrated adenoma is higher in younger group.

Disclosure: Nothing to disclose.

Aims and Methods: This study aimed to uncover the relevant driver genes maintaining EGFR-positive colorectal cancer cells, and to discover the efficiently therapeutic agents. EGFR-positive HCT116- and HT29-derived cancer stem-like cells (CSCs) were induced in vitro as studying models in this study. RNAseq technique following by pathway analyzation was used to identify the differentially expressed maintaining CSCs. Moreover, a panel containing 172 therapeutic agents targeting to the documental pathways of stem cells were applied to search for the efficient therapeutics against CSCs.

Results: RNAseq revealed that 654 genes were significantly up-regulated and 840 genes were down-regulated in the HCT116CSCs. Among the genes, notably, platelet-derived growth factor A (PDGFA) and signal transducer and activator of transcription 3 (STAT3) were relevant to Pathway in Cancer analyzed by using Pathway Analysis. Furthermore, the therapeutic screening indicated that the agents targeting to STAT3 and Wnt signaling pathways were efficient to reduce the cell viabilities of HCT116 and HT29 cells. Consequently, we figured out that inhibition of STAT3 by its specific inhibitors such as homoharringtonine and knockdow technique significantly reduced the formation and survival of the HT29-derived tumorspheres, whereas STAT3 phosphorylation was majorly regulated by EGFR to induce PDGFA and Wnt signaling cascade.

Conclusion: This study demonstrated the potential genes involving in the tumor sphere formation and survival in the selective EGFR-positive colorectal cancers. The data suggested that EGFR-STAT3 signaling pathway promoted and maintained the colorectal cancer stemness as a putative therapeutic target, where STAT3 may be through inducing PDGFA to activate Wnt signaling pathway.

Contact E-Mail Address: chenw3655@msn.com

Introduction: The outcome of interval colorectal cancer (ICRC) varied in previous studies without accounting for lead time bias.

Aims and Methods: This nationwide cohort analysis estimates expected years of life lost (EYLL) to adjust for lead time bias and comparison between patients with ICRC and detectable colorectal cancer (DCRC). Patients with colorectal cancer (CRC) registered in Taiwan Cancer Registry during 2002 to 2009 were enrolled, including 22,169 CRC confirmed within 6 months after colonoscopy grouped as ICRC (DCRC) and 1,653 CRC diagnosed during 6–60 months after a negative colonoscopy grouped as ICRC. All patients were followed up until the end of 2011. We simulated age- and sex-matched references from life tables in Taiwan National Vital Statistics using Monte Carlo method. Life-time survival of the cancer patients was obtained from extrapolation of logit transform of the survival ratio between cancer cohorts and age- and sex-matched references. The LE (life expectancy) and EYLL were calculated after adjustment for age at diagnosis and/or lead time bias. There is a linear trend for increasing proportion of ICRC from distal to proximal colon, which seems to corroborate with different cancer recurrence patterns along culture time.

Results: Comparing with DCRC, ICRC were predominately older age, more on proximal sites, and more endoscopic polypometry procedures (p < 0.001). Patients with ICRC had consistently shorter LEs than those of DCRC after stratification of CRC patients into stages. There is no such trend if the comparison is performed through EYLL, or adjustment for age at diagnosis and/or lead time bias. There is a linear trend for increasing proportion of ICRC from distal to proximal colon, which seems to corroborate with different cancer recurrence patterns along culture time.

Conclusion: The evidence corroborates the hypothesis that the worse long-term outcome or shorter LE of ICRC largely results from lead time bias.

Disclosure: Nothing to disclose.

P0406 ACTIVATION OF STAT3 MEDIATES SURVIVAL OF CANCER STEM CELLS VIA PDGFA SIGNALING

Introduction: Cancer stem cells are capable of cell division and survival against cancer therapies, leading to tumor progression and recurrence. The inhibitory agents against cancer stem cells may be efficient for eradicating tumors.

Aims and Methods: In this prospective study we cultured patient-derived tissue microfragments in stirred-tank culture systems (PDEs) - we studied culture viability (metabolic and morphologic evaluations), phenotype [gland and/or villi formation, mucin production, presence of tumor infiltrating lymphocytes (TILs), p53 staining, mismatch repair protein expression, microsatellite instability] and KRAS (exon 2) and BRAFV600E mutational status in in vitro cultures; we correlated culture viability and structure to the primary tumors.

Results: 11 CRCs were collected. All tumors were successfully cultured as PDEs for 28 to 122 days. Culture duration was determined by the frequency of sampling along culture time to assure a minimum PDE concentration. PDEs (N≥7/11) viable were used to determine drug efficacy, there are no available long-term validated models to test chemotherapy in patient-derived cultures, namely in the different carcinogenesis pathways.

Aims and Methods: We aim to develop an efficient methodology for culture of CRC samples originated from different carcinogenesis pathways.

Contact E-Mail Address: isaiarw@zoommail.pt

Introduction: Colorectal cancer (CRC) is the second most common cancer in developed countries. More than a quarter of these patients eventually receive chemotherapy. Several pathways leading to CRC are currently recognized, which may impact on therapy success. Although both short-term culture of tumor sections and xenotransplantation have been used to determine drug efficacy, there are no available long-term validated models to test chemotherapy in patient-derived cultures, namely in the different carcinogenesis pathways.

Aims and Methods: We aim to develop an efficient methodology for culture of CRC samples originated from different carcinogenesis pathways.

Introduction: Colorectal cancer (CRC) is the second most common cancer in developed countries. More than a quarter of these patients eventually receive chemotherapy. Several pathways leading to CRC are currently recognized, which may impact on therapy success. Although both short-term culture of tumor sections and xenotransplantation have been used to determine drug efficacy, there are no available long-term validated models to test chemotherapy in patient-derived cultures, namely in the different carcinogenesis pathways.

Conclusion: In this prospective study we cultured patient-derived tissue microfragments in stirred-tank culture systems (PDES) - we studied culture viability (metabolic and morphologic evaluations), phenotype [gland and/or villi formation, mucin production, presence of tumor infiltrating lymphocytes (TILs), p53 staining, mismatch repair protein expression, microsatellite instability] and KRAS (exon 2) and BRAFV600E mutational status in in vitro cultures; we correlated culture viability and structure to the primary tumors.

Results: 11 CRCs were collected. All tumors were successfully cultured as PDES for 28 to 122 days. Culture duration was determined by the frequency of sampling along culture time to assure a minimum PDE concentration. PDES (N = 11/11) retained their origins’ architecture. There was always viable tumor for at least 28 days (~ 46 days, range 28-87 days) and for most cases (N = 7/11) viable stroma was retained for as long as the neoplastic cells. Capillaries were not preserved. PDES (N = 10/11) considerably lost tumor architectural, stroma cellularity and inflammatory cells, specifically TILs, at the first histological evaluation (days 7-11), but less significantly thereafter. After the first week of culture, PDE tumor cells progressively acquired a senescent phenotype. PDES (N = 10/11) replicate the original tumors’ immunohistochemical and genetic key features. One PDE showed a KRAS mutation undetected in the primary tumor, from day 0; p53 staining was also consistently different in the PDE.

Conclusion: PDE dynamic culture is an efficient method to culture human CRC. Overall the key pathological features of the primary tumors are retained over time, which supports the potential use in drug predictive assays. Divergent results may be due to intratumoral heterogeneity and optimization in tumor collection may be required to improve PDE representation of the primary tumor.

Disclosure: Isadora Rosa reports personal fees and/or non-financial support from MSD, Abbvie, Ferring, Dr Falk Pharma, Pharmakern, Hospira, Janssen and Takeda, outside the submitted work.
Lymphovascular invasion was present in 4/5 (80%) and perineural invasion in 3/5 (60%).

**Results:**

The detection of both EFEMP1 and CDH13, using real-time PCR, was associated with increased risk of CRC in both genders. The combined detection of both markers was highly correlated with the presence of CRC, with a positive predictive value of 95%.

**Conclusion:** The detection of EFEMP1 and CDH13 in the early stages of CRC could be a useful tool for the early detection of CRC, especially in women.

**Disclosure:** Nothing to disclose.

**P0408 HDAC SELECTIVE INHIBITOR, ACY1215, INHIBIT COLON CANCER CELL LINE HCT116**

Y Tan, S Zhang, J Hua, D Liu

The Second Xiangya Hospital, Central South University, Gastroenterology, Changsha, China

Contact E-Mail Address: tanyyong@csu.edu.cn

**Introduction:**

Colorectal cancer is one of the most common cancers leading cause of death around the world, and 5-FU is the most common used chemotherapeutic drugs for colorectal cancer. However, resistance do occur. HDACs is a unique member of HDACs, and is involved in regulating diverse key biological processes including cell motility, cell division, protein trafficking, and apoptosis, thus playing important role in carcinogenesis. HDAC inhibitors have emerged as promising agents for the treatment of various forms of cancer, and ACY1215, the first oral HDAC6 inhibitor, has shown promising results for treatment of multiple myeloma in phase I and II clinical trials, however little is known about its role in colorectal cancer.

**Aims and Methods:**

We aimed to explore the effect of Rocinolast (ACY1215), a specific HDAC6 inhibitor, on the cell growth, migration and apoptosis of HCT116 cells, as well as its influence on the chemotherapeutic effect of 5-Fluorouracil (5-FU) on colon cancer.

**Results:**

When treating HCT116 cells with different concentration of ACY1215, and explore its effect on cell viability, proliferation, cell migration and apoptosis, and explore the potential mechanism of ACY1215 via detecting some cell signal related protein by western blot. And then explore the influence of ACY1215 treatment on the chemotherapeutic effect of 5-FU.

**Results:**

After treating HCT116 cells with ACY1215, the cell viability, colony formation, wound closure and migrated cell numbers were significantly reduced with the increasing concentration of ACY1215. When the proportion of apoptosis cells were significantly increased with the increased concentration of ACY1215 (p < 0.05), as well as the expression of apoptosis-related protein (PARP and Cleaved-Caspase 3). After treating HCT116 cells with ACY1215, the expression of p-ERK and ERK were decreased, while no obvious changes were noticed regarding the expression of MEK and ERK. Treating HCT116 cells with ACY1215 and/or 5-FU, we found that the cell viability, colony formation, wound closure and migrated cell numbers were significantly reduced when compared with control group, or correspond drug, or correspond drug with combined drugs (p < 0.05). The same tendency was noticed in regarding to the expression of apoptosis related protein (PARP and Cleaved-Caspase 3).

**Conclusion:** HDAC specific inhibitor, ACY1215, could inhibit the cell growth, proliferation and migration, and promote apoptosis of HCT116 colon cancer cells. ACY1215 exhibits its tumor suppression role via inhibition of the MEK/ERK signal pathway. ACY1215 may enhance the chemotherapeutic effect of 5-FU on colon cancer cells.

**Disclosure:** Nothing to disclose.

**Introduction:**

Colorectal cancer (CRC) is extremely rare in pediatric patients. A poor outcome has been reported in parallel with unfavorable prognostic factors.

**Aims and Methods:**

We aimed to characterize at clinical, pathological and molecular level a group of pediatric CRC patients (< 18 years) - and evaluate overall and disease-free survival.

**Results:**

Included pediatric CRC patients diagnosed from January 2002 to January 2016. Clinical data, tumor features, and survival were evaluated.

Microsatellite instability (MSI) status, loss of heterozygosity for the microsatellite Bethesda microsatellite markers and expression of the DNA mismatch repair (MMR) proteins were analyzed. Germline mutation analysis was performed. All tumors were MMR-proficient.

**Conclusion:**

Pediatric CRC is a rare entity, with distinct histological and molecular presentations, resembling features from adult CRC. This study demonstrates the importance of comprehensive genetic analysis in pediatric CRC.

**Disclosure:** Nothing to disclose.

**Introduction:**

As an essential part in stromal cells, cancer-associated fibroblast (CAF) plays an important role in the tumor microenvironment and exerts promoting effect in colorectal neoplastic progression. However, the detailed molecular mechanisms remain largely unknown.

**Aims and Methods:**

In this study, we proposed to reveal the oncogenic role of CAF in colorectal cancer (CRC) progression. The primary culture was employed for isolation of CAF and adjacent normal fibroblast (NF). The CRC cells were treated with conditional medium (CM) from NF and CAF for the assessment of cell proliferation rate and invasion ability. RNA-Seq analysis was applied to identify the differentially expressed genes in 3 paired NF and CAF samples. The candidate genes were validated by qRT-PCR in 18 paired primary samples and 7 top genes, TNFSF4 and IGF2, were selected for functional studies.

**Results:**

In primary culture, CAF-produced CM exhibited oncogenic function through promoting CRC cell proliferation and invasion. TNFSF4 and IGF2 were screened out showing the highest expression in CAFs compared with NFs with 14 and 12-time upregulation respectively. qRT-PCR confirmed the abundance of TNFSF4 (p < 0.0001) and IGF2 (p = 0.0056) in CAF.

**Conclusion:**

Immunohistochemistry staining on the tissue microarray demonstrated that TNFSF4 was predominantly expressed in fibroblasts but IGF2 was located both in the cancer cells and fibroblasts. Their receptors, OX40 and IGFFR were expressed in immune cells and cancer cells respectively. In the functional studies, both rhIGF2 and IGF2 CM promotes CRC cell proliferation and invasion in vitro.

**Disclosure:** All authors have declared no conflicts of interest.
Results: CCS groups included CCS1: CDX (+) and MSI-L/MSS (14 cases), CCS2: MSI-H (5 cases), and CCS3: CDX (+) and MSI-L/MSS (5 cases). Invasive cancer was significantly higher in CCS3 than CCS1 (CCS1:CCS3, 5/14 vs. 5/5, p = 0.0048). K67 LI and epithelial serration were higher in CCS3 than in CCS1 (CCS1:CCS3, 63.4±4.0 vs. 83.0±5.8, 3.14±5/5, p = 0.0048, 0.031). CCS2 showed the highest mutation number, whereas KRAS and/or BRAF mutation number were higher in CCS3 than CCS1 (2.14 vs. 4.5, p = 0.038).

Conclusion: Early-stage SACs can be classified into 3 molecularly distinct subtypes with different clinicopathological and genetic characteristics.

P0412 MB2D AND EZH2 REGULATE SFRP1 EXPRESSION WITHOUT AFFECTING ITS HYPERMETHYLATION IN COLORECTAL CANCER CELL LINE

J Qi, J Yu
Zhejiang Hospital of Wuhan University, Wuhan, China

Contact E-Mail Address: qideli@163.com

Introduction: The Secreted frizzled related proteins 1 (SFRP1) as extracellular inhibitors of Wnt signaling is downregulated by high frequency of promoter hypermethylation in the early stage of colorectal tumorigenesis. PCG proteins and MBD proteins important for gene epigenetic regulation have the ability to regulate gene expression. We aim to figure out the role of the specified PCG and MBD proteins in the regulation of SFRP1 gene expression.

Aims and Methods: The methylation status and mRNA expression of SFRP1 in CRC cell lines and human embryo intestinal mucosa cell CCC-HHE-2 are analyzed by Methylation-specific PCR (MSP) and real-time qPCR. The combination of MSP with qPCR proteins with SFRP1 gene is studied. The related genes are screened by chromatin immunoprecipitation (ChIP). We knock down related genes by RNA interference to clear its role in the regulation of SFRP1 gene expression and the effect on proliferation of colorectal tumor cells.

Results: The promoter of SFRP1 was unmethylated in control CRC cell lines and partly methylated in normal cell line CCC-HHE-2. The mRNA expression level of SFRP1 was down-regulated significantly in CRC cell lines compared to normal cell line (p < 0.05), but none of BMI1, EZH2 and MB2D proteins bound to SFRP1 in HCT116 (p > 0.05). The expression of SFRP1 is reactivated by MB2D siRNA (p < 0.05), but not by EZH2 siRNA in SW480 (p > 0.05). However, knockdown of the MB2D and EZH2 together can restore SFRP1 gene expression more effectively and inhibit the proliferation of SW480. All of those inhibitions cannot be provided by MBD2 and EZH2 together can restore SFRP1 gene expression more efficiently and inhibit the proliferation of SW480. All of those inhibitions cannot be increased by knockdown of SFRP1 promoter methylation.

Conclusion: MB2D and EZH2 regulate SFRP1 expression without affecting its hypermethylation in colorectal cancer cells.

P0413 IDENTIFICATION OF NOVEL THERAPEUTIC TARGETS IN THE TUMOR MICROENVIRONMENT OF COLORECTAL CANCER

E Yamamoto, A Yorozu, H Aoki, H Suzuki
Sapporo Medical University, Dept. of Molecular Biology, Sapporo, Japan

Contact E-Mail Address: eiichiro@na.so-net.ne.jp

Introduction: Cancer microenvironment, including tumor endothelial cells (TECs) and cancer associated fibroblasts (CAF s), plays an important role in the pathogenesis of cancer and is considered as a potential therapeutic target.

Aims and Methods: We aimed to understand the molecular mechanism of microenvironment of colorectal cancer (CRC) and to identify novel therapeutic targets. The gene expression of normal cells in primary CRC and performed multivariate outcome analysis. Stromal cells and epithelial cells from surgically resected primary CRC (n = 14) and corresponding normal colonic tissues (n = 14) by using CD146 and EpCAM as markers. RNA sequencing (RNA-seq) was performed in 3 pairs of normal and tumor stromal cells. Expression of the gene was validated by quantitative RT-PCR (qRT-PCR) and immunohistochemistry. To analyze the gene function, human umbilical vein endothelial cells (HUVECs) and cultured CAFs were transfected with specific siRNAs after which cell viability assays and gene expression microarray were performed.

Results: RNA-seq analysis identified a series of 18 genes upregulated in tumor stromal cells isolated from primary CRC tissues. Through validating the results by qRT-PCR and immunohistochemistry, we identified AEBP1, as a novel candidate of gene. AEBP1 is expressed in TECs and CAFs in CRC tissues, and that the expression was higher in the invasive front. The Cancer Genome Atlas (TCGA) datasets revealed that higher expression of AEBP1 is associated with worse overall survival of CRC patients. Expression of AEBP1 was also upregulated in HUVECs treated with TNM obtained from CRC cell lines. Knockdown of AEBP1 in HUVECs suppressed in vitro tube formation. Knockdown of AEBP1 in HUVECs and CAFs suppressed cell proliferation and induced G1 cell cycle arrest. Microarray analysis revealed that knockdown of AEBP1 in HUVECs significantly affected the expression signature of angiogenesis-related genes including POSTN and SFRP1. To confirm our findings in vivo, we co-transplanted CRC cells with HUVECs into nude mice. We found that knockdown of AEBP1 in HUVECs resulted in reduced micro vessel formations in the xenograft tissues. Moreover, we found that injection of siRNAs targeting mouse AEBP1 suppressed in vitro tumor growth.

Conclusion: Our results suggest that AEBP1 may play an important role in the microenvironment in CRC, and that it could be a potential therapeutic target.

P0414 SYSTEMATIC REVIEW AND META-ANALYSIS: DIAGNOSTIC ACCURACY OF QUANTITATIVE FECAL IMMUNOCHEMICAL TESTS FOR COLORECTAL CANCER DETECTION IN SYMPTOMATIC PATIENTS

N Pin Vieito,1,2 S Zarragaños,1,2 J Cubilla1,2
1Complexo Hospitalario Universitario Ourense, Department of Gastroenterology, Ourense, Spain
2Instituto de Investigación Sanitaria Galicia Sur, Ourense, Spain

Contact E-Mail Address: joaquin.cubilla.fernandez@sergas.es

Introduction: The quantitative fecal immunochromostatic test (FIT) is a non-invasive biomarker for the early detection of colorectal cancer (CRC). Recently, the National Institute for Health and Care Excellence (NICE) has recommended the adoption of FIT in primary care to guide referral for suspected colorectal cancer in people without rectal bleeding who have unexplained symptoms but do not meet the suspected cancer pathway referral (1).

Aims and Methods: Our goal is to assess the diagnostic accuracy of FIT for CRC detection in symptomatic patients. 2 searches independently reviewed online databases including MEDLINE, Embase expanding the search to bibliography and authors of relevant studies. All studies evaluating the diagnostic accuracy of quantitative FIT for CRC in symptomatic patients until May 2017 were included. Studies were classified by FIT threshold, brand, percentage of symptoms and CRC prevalence. Quality of studies was evaluated, and global sensitivity and specificity were estimated in addition to the ROC curve (sROC) taking the area under the curve (AUC) as a global precision estimator in those subgroups formed by at least three studies, using a random effect model. Heterogeneity was determined by means of the Q statistic of Cochran. Threshold effect was examined by calculating Spearman’s rank correlation.

Results: 13 studies were included in our review accumulating a sample of 12,584 patients (52% women). Data from 7 cohorts were obtained for patients scheduled consecutively to undergo elective colonoscopy due to several indications, with their CRC prevalence ranging from 0.4 to 7.1%. The remaining 6 were carried out on purely symptomatic patients with CRC prevalence ranging from 2.3 to 16.8%.

The pooled sensitivity for CRC detection of OC-Sensor® at the 0, 10 and 20 μg/g cut-off was 98% (95% confidence interval CI 96–99%), 91% (95% CI 88–93%) and 90% (95% CI 87–93%), respectively. Conversely, pooled specificity at the same thresholds was 36% (95% CI, 34–37%), 80% (95% CI 79–81) and 83% (95% CI 81–84%), respectively. At the threshold with the best discriminatory ability (20 μg/g of feces) the AUC was 0.93 (95% CI, 0.91–0.96). The number of available studies performed with the OC-Sensor® allowed for the conduct of a subgroup analysis based on the prevalence of CRC and the percentage of symptoms at the 10 μg/g cut-off. Pooled sensitivities were higher in the studies reporting a CRC prevalence ≥3% (92%, 95% CI; 89–94%) and in those performed only on a symptomatic population (94%, 95% CI, 91–97%); Conversely, the test’s specificity in those subgroups was 70% (5% CI, 68–71%) and 66% (95% CI, 64–67%), respectively.

3 studies using OC-Sensor® with the same threshold identified 79% (95% CI; 76–81%) of patients with significative colonic lesions (SCL), with a 70% (95% CI; 68–72%) specificity, respectively.

Only 3 studies evaluated HM-Jack® at different thresholds. The AUC was 0.88 (95% CI, 0.77–0.98). There was substantial heterogeneity between studies specifically in the pooled specificity estimates.

Conclusion: The diagnostic accuracy of FIT is highly sensitive for CRC detection in symptomatic patients. However, its global accuracy may depend on the prevalence of another SCL. Caution is recommended when using it to rule out CRC in this setting.

Disclosure: The work described in this abstract has been previously presented as an oral presentation at a Spanish scientific meeting (Asociación Española de Gastroenterología) in Madrid in March 2018.

Introduction: The quantitative immunochromical fecal occult blood test (FIT) has proved its worth on both CRC screening and in the timely assessment of patients with symptoms of lower bowel disease (1). However, its use in routine clinical practice remains unknown, as does its accuracy to detect CRC in this setting.

Aims and Methods: Our purpose was to describe the use of FIT in 2 Spanish regions and estimate its accuracy in real practice, in order to consider whether or not it is comparable to theoretical values.

Retrospective observational study with long-term follow-up. We included all subjects from the metropolitan area of San Sebastian (SS) and the province of Ourense (Ou) who had been performed a FIT determination (OC-Sensor®) requested at their primary care center between January 2009 and May 2015. CRC diagnosis was determined in the following 2 years using discharge information obtained from the national surveillance system for hospital data. Conjoint Minimo Basico de Datos (CMBD), provided by the Ministry of Health. Global accuracy for detecting CRC was assessed by means of the receiver operating characteristics (ROC) curve and its area under the curve (AUC). Sensitivity and specificity were calculated using 10 and 20 g/g feces as thresholds. Subgroup analysis were conducted using 10 μg/g cut-off to assess differences between center, age, sex and test indication (CRC screening / symptom evaluation).

Results: During the studied period, at least 1 FIT determination was requested to 22,819 patients (54.1% women). 5,265 people were from SS and 17,554 from Ou with significant differences with regard to age (SS=60.4±16.3, Ou=64.9±16.1; p<0.0001) and CRC diagnosis was determined in the following 2 years using discharge information obtained from the national surveillance system for hospital data. Conjoint Minimo Basico de Datos (CMBD), provided by the Ministry of Health. Global accuracy for detecting CRC was assessed by means of the receiver operating characteristics (ROC) curve and its area under the curve (AUC). Sensitivity and specificity were calculated using 10 and 20 g/g feces as thresholds. Subgroup analysis were conducted using 10 μg/g cut-off to assess differences between center, age, sex and test indication (CRC screening / symptom evaluation).

With regard to subgroup analysis, no differences were found in sensitivity between regions (SS 85.0%, CI 95% 84.5–85.6; Ou 84.5% CI 95% 83.8–85.3; p=0.72), age (< 50y 85.0%, CI 95% 84.0–86.0, ≥50y 85.5% CI 95% 84.9–86.2; p=0.21), sex (men 90.5%, CI 95% 89.0–91.9, women 89.5% CI 95% 88.5–89.3, p=0.57) or CRC diagnosis (SS 10%, Ou 2% <p=0.001) or CRC diagnosis (SS 10%, Ou 2% <p=0.001). The reason for requesting the test was available for SS subjects (53.9% symptom evaluation). Subgroup analysis were conducted using 10 μg/g cut-off to assess differences between center, age, sex and test indication (CRC screening / symptom evaluation).

Conclusion: The AUC of FIT to detect CRC was 0.85 (CI 95% 0.84-0.87). Sensitivity and specificity at the 10 and 20 g/g cut-offs were 91% (CI 95% 87.6–93.5) vs 88% (CI 95% 84.3–90.9) and 77.8% (CI 95% 77.2–78.4) vs 85.2% (CI 95% 84.7–85.8) respectively.

Introduction: Effective colonoscopy requires successful bowel preparation. ‘Adequate’ preparation allows detection of lesions >5 mm and has been defined as a Boston Bowel Preparation Scale (BBPS) score of ≥2 per segment. This post hoc analysis determined the relationship between BBPS scores and adenoma and polyp detection in patients who had identified scores in each of the 3 colon segments, using pooled data from 3 identically designed Phase 3, multicentre, randomised trials.

Aims and Methods: Analyzed patients had: treatment-blinded central reader assessed BBPS scores where the BBPS score was identical in each segment, and recorded polyp and adenoma counts. Patients were stratified to assess the relationship between low-quality cleansing (BBPS of 1–1,1–2 or ≥2–2) or high-quality cleansing (BBPS of 3–3,3–4, and ADR and PDR. A logistic regression (LR) model was fitted to assess whether ≥1 polyps and, separately, ≥1 adenomas, were detected including the BBPS score group and study as fixed effects.

Results: 1170 patients were analysed (Table 1). For low, adequate and high-quality cleansing, the PDRs were: 40.7%, 41.7%, 54.8%, and the ADRs were: 27.8%, 26.0% and 42.8%. The odds ratio (OR) for detection were significantly higher with high-quality versus adequate cleansing (PDR OR: 1.60, 95% confidence interval [CI] 1.14–2.24, p<0.0067; ADR OR: 1.97, 95% CI 1.39–2.80, p<0.0001). LR analysis revealed a significant correlation between BBPS score and PDR (p=0.0239) and ADR (p=0.0006).

Conclusion: In patients who had uniform low, adequate or high-quality cleansing in each respective colon segment, there was a strong correlation between higher cleansing scores and increased PDR and ADR.

Abstract No: P0416

Aims and Methods: Patients aged 18-85 years were included if they had fully reported HCS scores, adenoma and polyp counts, and also identical segmental HCS scores (range 0-4) in all 5 HCS colon segments. A logistic regression analysis was performed using the Cox proportional hazard (CH) (Cox) and p-value (p) for the resulting trend in lesion detection, when segmental HCS scores increased incrementally from 0 to 4.

Results: 469 patients were included in this analysis (Table 1). When uniform segmental HCS scores were increased from 0, 1, 2, 3, and 4, the resulting ADRs increased continuously (0%, 10.0%, 25.6%, 32.4% and 53.8%) as did the PDRs (0%, 30%, 43.5%, 51.4%, and 61.5%). The corresponding OR (CI) and [P] were, for ADR 1.61 (1.182-2.199) [0.0026], and for PDR 1.38 (1.021-1.863) [0.0361].

Conclusion: ADR and PDR increased continuously with improved colon cleansing quality. There was a strong association between uniform segmental HCS scores and both ADR and PDR.

Introduction: Colorectal cancer (CRC) is the third main cause of cancer mortality. Around 75% of CRC are sporadic and they usually develop without symptoms. Therefore, some countries are implementing CRC national screening policies in order to detect lesions at an early stage by using non-invasive tools. One of the most common tools is the faecal immunochemical test (FIT). Despite affordability, FIT shows a low sensitivity for precancerous lesions (29%) and a low positive predictive value (8%), which produces a high rate of false positive results. Hence, CRC-screening organizations are demanding new, non-invasive tools, capable of decreasing false positive rates, thus reducing the number of unnecessary colonoscopies. The aim of this study was to develop a new, non-invasive CRC screening tool based on bacterial faecal markers, which in combination with FIT (thereby named RAID-CRC), could reduce the false-positive rate.

Aims and Methods: We performed the FIT analysis (OC-Sensor® Kit) and the bacterial markers analysis (CR1-CRC10) in stool samples from individuals with normal colonoscopy (167), non-advanced adenomas (88), advanced adenomas (30) and CRC (48). All participants showed CRC-associated symptoms. The RAID-CRC algorithm was designed using machine learning technology.

Results: Performance of FIT for advanced neoplasia (i.e. advanced adenoma and CRC) was determined by using the cut-off value established in Catalonia (OC-Sensor®, 20 μg Haemoglobin of faeces) for a population-based screening approach. Sensitivity and specificity values of 83% and 80%, respectively, and positive and negative predictive values of 56% and 94%, respectively, were obtained. When RAID-CRC was used, the corresponding values were 80% and 90% for sensitivity and specificity, respectively, and 70% and 94% for positive and negative predictive values, respectively, resulting in a 50% reduction of the false-positive rate.

Conclusion: RAID-CRC is a promising tool for CRC screening because of its non-invasiveness, its low cost and its capacity for lowering the number of false-positive results associated with the use of FIT. Therefore, RAID-CRC use would lead to a reduction up to 30% of unnecessary colonoscopies and their derived costs. However, since our study was based on a small sample of individuals, this new approach warrants to be validated in a screening scenario.

**P0419 CLINICAL AND PATHOLOGICAL OVERLAP AMONG THE HAMARTOMATOUS POLYPOSIS SYNDROMES CAN RESULT IN ERRONEOUS DIAGNOSIS**

O Gilad, G Rozner, S Aharon-Kaspinski, N Fliss -Isaksoy, N Gluck, R Kariv Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Contact E-Mail Address: ophir.gilad@gmail.com

Introduction: Hamartomatous polyposis syndromes (HPS) are a group of rare autosomal-dominant syndromes, associated with hamartomatous polyps and gastrointestinal (GI) tract malignancies, including: Juvenile polyposis (JPS), Peutz-Jeghers syndrome (PJS) and Cowden disease (CD). There is a known clinical and histological overlap between syndromes. Appropriate diagnosis dictates cancer prevention surveillance for the proband and family carriers. Yet, more than 50% of clinically diagnosed cases have no genetic diagnosis.

Aims and Methods: We aimed to describe phenotype, genotype, histology and outcomes of individuals/families with HPS, study overlap between syndromes and erroneous diagnosis according to genetic findings.

Retrospective cohort-study of consecutive HPS patients. Demographic, clinicopathological and genetic data were obtained from computerized-medical-records.

Results: 52 individuals from 34 families were included. Phenotypic, oncologic and genetic findings of the 3 syndromes are described in Table 1. Clinical manifestations included mainly rectal bleeding (49% JPS, 23% PJS, 25% CD) and bowel obstruction (46.15% JPS, 11.4% JPS). Pathological report varied widely, with 75% of JPS, 61% of PJS and 50% of CD having a polyp diagnosis different from the syndrome hallmark, with some patients having up to 6 different types of polyps. Overall 22/52 (42.3%) of patients had a histological diagnosis of adenoma during follow up (48.5% of JPS, 38.4% of PJS and 25% of CD). 4 patients had an initial incorrect diagnosis, with subsequent review of pathology and genetic testing unveiling the correct syndrome. Gastrointestinal cancer history was positive in 65%, 40% and 50% of JPS, PJS and CD families, respectively. 5 patients developed cancers (2 gastrointestinal, 1 thyroid, 1 breast and 1 with both breast cancer and liposarcoma of the chest). 18 (34.6%) patients tested positive for mutations in either STK11, PTEN, SMAD4 or BMPR1A. 2 additional patients were found to harbour novel gene mutations in AKT1 and TM7SF3. Sanger sequencing had a positive detection rate of 45.4% while next generation sequencing (NGS) had a 100% detection rate.

Conclusion: HPS present various phenotypes with apparent redundancy in histological diagnosis, requiring pathology review. Cancer rates are low at this cohort, potentially due to the young mean age. The NGS era should shed light on further candidate-genes and genetic alterations in order to better understand cancer related mechanisms and prevent malignancy.

**P0420 ERCC6L PROMOTES CELL GROWTH AND INVASION IN HUMAN COLORECTAL CANCER**

Y Xiao, J Yu, F Wang, M Li, J Liu, J Qi Zhongnan Hospital of Wuhan University, Gastroenterology, Wuhan, China

Contact E-Mail Address: qiujian@whu.edu.cn

Introduction: Excisome repair genes (ERCC6L, 66), a newly discovered DNA helicase, has been discovered highly expressed in diverse human cancers. However, the precise role of ERCC6L in colorectal cancer (CRC) remains unclear.

Aims and Methods: This study aimed to explore the potential role of ERCC6L in the development and progression of CRC. Real-time quantitative polymerase chain reaction (qRT-PCR) and western blot were used to detect the expression of ERCC6L in 30 colorectal cancer patients. 9 pairs of CRC tissues were examined.
by immunohistochemistry. The function of ERCC6L in cell proliferation, cycle, apoptosis, invasion and colony-forming ability was examined in CRC cell lines. Results: ERCC6L was highly expressed in CRC tissues and CRC cell lines. The expression of ERCC6L was related to tumor size, but not to other clinical features such as age, gender, differentiation and clinical stage. We found that silencing of ERCC6L by small interfering RNA (siRNA) remarkably inhibited the proliferation rate and colony-forming ability of CRC cell lines. Flow cytometry analysis showed that knockdown of ERCC6L in CRC cells blocked the cell cycle progression and more cells were delayed in G0/G1 phase without affecting apoptosis. Moreover, knockdown of ERCC6L remarkably decreased the invasion number of CRC cells compared with the cells treated with negative control. Conclusion: Our results suggest that ERCC6L can stimulate cancer cell proliferation by promoting cell cycle progression, and it may be a potential target for cancer therapy.

Introduction: A simple, low invasive test with high sensitivity for both colorectal cancer and advanced precancerous lesions might increase uptake and adherence rates, which could improve clinical outcomes. Thanks to the technological advances, these days metabolomics technology offers a powerful tool for biomarker discovery.

Aims and Methods: In this study we have performed a targeted ultra-performance liquid chromatography/time-of-flight mass spectrometry (UPLC-(TOF) MS)-based metabolomics approach to identify faecal biomarkers for the detection of patients with advanced neoplasia. A cohort of 80 patients with advanced neoplasia (40 advanced adenomas and 40 cancers) and 49 healthy subjects were enrolled in the study. We evaluated the faecal levels of 105 metabolites including glycerolipids, glycerophospholipids, sterol lipids and sphingolipids.

Results: We found a panel of 18 metabolites that were significantly altered in patients with advanced neoplasia compared to healthy controls. Combinations of seven of these metabolites including ChoE(18:1), ChoE(18:2), ChoE(20:4), PE(16:0/18:1), SM(42:3) and TG(54:1) discriminated advanced neoplasia with a predictive model that provide an area under the curve (AUC) value of 0.821. Furthermore, the levels of the cholesteryl esters correlated positively with the faecal haemoglobin concentration and its inclusion in the metabolomics signature improved the predictive model to an AUC of 0.885.

Conclusion: Our results suggest that ERCC6L can stimulate cancer cell proliferation by promoting cell cycle progression, and it may be a potential target for cancer therapy.

Pedunculated morphology is independently associated with a better prognosis (OR 0.60; 95% CI 0.38–0.98, p = 0.007). The association between morphology and the primary composite endpoint adverse oncologic outcome adjusted for clinical variables, histological variables and treatment approach were defined as lymph node metastasis, distant metastasis, local recurrence or residual tissue. Secondary end-points were metastasis, recurrence and incomplete resection.

Results: In total, 1,656 patients with T1 CRC with a median follow-up time of 42.5 months (IQR 18.5–77.5) were included. Adverse oncologic outcomes were observed in 9.3% (67/723) of pedunculated T1 CRCs vs 16.6% (155/933) of non-pedunculated T1 CRCs. Pedunculated morphology was independently associated with a decreased risk for adverse oncologic outcomes (adjusted OR 0.61; 95% CI 0.43–0.86; p = 0.005). Metastasis, incomplete resection and recurrence were observed in 8.5%, 6.5% and 5.4% of patients, respectively. Pedunculated morphology was also independently associated with a reduced risk for metastasis (adjusted OR 0.41; 0.25–0.69; p = 0.003), incomplete resection (adjusted OR 0.60; 95% CI 0.38–0.98; p = 0.03) and recurrence (adjusted HR 0.51; 95% CI 0.32–0.84; p = 0.007).

Conclusion: Pedunculated morphology is independently associated with a better oncologic outcome with no additional treatment. Incorporating morphology in future risk assessment is therefore likely to refine risk prediction in T1 CRC, thereby improving patient selection for surgery.

P0424 LONG-TERM ONCOLOGIC OUTCOMES OF SELF-EXPANDING METALLIC STENTS AS A BRIDGE TO SURGERY IN MALIGNANT LEFT-SIDED COLON OBSTRUCTION COMPARED WITH EMERGENCY SURGERY
S.Y Oh
Ajou University School of Medicine, Suwon, Korea (Republic of)

Contact E-Mail Address: kpsomy@gmail.com

Introduction: Self-expandable metallic stents (SEMS) are used as a bridge to surgery in malignant left-sided large bowel obstruction (MLO). However, the oncologic outcome after endoscopic stenting remains to be assessed.

Aims and Methods: The aim of this study is to compare the oncologic outcomes of SEMS with those of emergency surgery for MLO. A database of MLO between January 2001 and December 2012 were reviewed. They were divided into those who underwent bridge-to-surgery with SEMS and those who undergone emergency surgery. The 2 groups were compared in terms of disease-free survival (DFS) and overall survival (OS).

Results: 93 patients underwent SEMS and 41 patients underwent ES. Clinicopathological features did not differ significantly between the SEMS and ES groups. (28 (30.0%) patients with sufficient recurrence in SEMS group and 14 (31.4%) patients suffered recurrence in ES group. There were no differences in 5-year DFS (67.6% vs. 64.6%; p = 0.761) and OS rates (71.0% vs. 64.9%; p = 0.554) between the 2 groups.

Conclusion: The SEMS as a bridge to surgery is equivalent to emergency surgery for MLO with regards to oncologic safety.

Saitama Cancer Center, Department of Gastrointestinal Surgery, Ina-city, Japan

Contact E-Mail Address: anzaih-sur@h.tokyo.ac.jp

Introduction: Coagulation pathways are activated in patients with malignancies. Precancerous versus non-pedunculated CRC have not been performed and current risk stratification for adverse events such as lymph node metastasis is based on histology only.

Aims and Methods: We aimed to compare adverse oncologic outcomes of pedunculated versus non-pedunculated T1 CRCs. Patients diagnosed with T1 CRC between 2000 and 2014 in 14 Dutch hospitals were included. We evaluated the association between morphology and the primary endpoint adverse oncologic outcome adjusted for clinical variables, histological variables and treatment approach. Adverse oncologic outcomes were defined as lymph node metastasis, distant metastasis, local recurrence or residual tissue. Secondary end-points were metastasis, recurrence and incomplete resection.

Results: In total, 1,656 patients with T1 CRC with a median follow-up time of 42.5 months (IQR 18.5–77.5) were included. Adverse oncologic outcomes were observed in 9.3% (67/723) of pedunculated T1 CRCs vs 16.6% (155/933) of non-pedunculated T1 CRCs. Pedunculated morphology was independently associated with a decreased risk for adverse oncologic outcomes (adjusted OR 0.61; 95% CI 0.43–0.86; p = 0.005). Metastasis, incomplete resection and recurrence were observed in 8.5%, 6.5% and 5.4% of patients, respectively. Pedunculated morphology was also independently associated with a reduced risk for metastasis (adjusted OR 0.41; 0.25–0.69; p = 0.003), incomplete resection (adjusted OR 0.60; 95% CI 0.38–0.98; p = 0.03) and recurrence (adjusted HR 0.51; 95% CI 0.32–0.84; p = 0.007).

Conclusion: Pedunculated morphology is independently associated with a better oncologic outcome with no additional treatment. Incorporating morphology in future risk assessment is therefore likely to refine risk prediction in T1 CRC, thereby improving patient selection for surgery.

Introduction: Little is known about the long-term outcomes of endoscopically resected rectal neuroendocrine tumors (NETs).

Aims and Methods: The present study aimed to investigate treatment strategies and long-term outcomes of endoscopic resection of small rectal NETs and long-term outcomes of endoscopically resected rectal NETs. We analyzed medical records of patients who underwent ER for rectal NETS from January 2005 to December 2016. The clinicopathological characteristics of these lesions were analyzed and long-term outcomes were evaluated.

Results: A total of 322 patients were studied. The complete and curative resection rate were 76.4% and 55.9%, respectively. Rectal NETs initially resected as polyps and treated with conventional EMR were observed more frequently in the curative resection group (p = 0.041 and p = 0.012, respectively). After ER, only 44 of the 142 patients (31.0%) who did not meet the criteria for curative resection received additional salvage treatment. In multivariate analysis, lesions diagnosed via biopsies (OR, 0.096; p = 0.002) or suspected as NETs initially (OR, 0.04; p = 0.001) were less likely to undergo additional treatment. Positive lymphovascular invasion (OR 61.71; p < 0.001), positive OR 75.993; p < 0.001, or indefinite OR 13.203; p = 0.001) resection margins were more likely to undergo additional treatment. Although lymph node metastasis was found in 6 patients, none experienced local or metastatic tumor recurrence during the median follow-up of 40.49 months.

Conclusion: Long-term outcomes after ER for rectal NETS were excellent. The prognosis showed favorable outcomes regardless of whether patients receive additional salvage treatment.

P0427 IMPACT OF PRIMARY TUMOR LOCATION AS A PREDICTIVE FACTOR IN CYTOTOXIC ANTI-CANCER AGENT FOR COLORECTAL CANCER (CRC) BASED ON COLLAGEN GEL DROPLET-EMBEDDED DRUG SENSITIVITY TEST (CD-DST)

Introduction: We have reported the usefulness of CD-DST for the individualization of first-line treatment in CRC (UEGW: 2014; P1538, 2015; P1681, 2016; P0929, 2017; P0466).

In recent years, primary tumor location in CRC as a predictive factor has attracted attention. Several reports have recently addressed the predictive impact of primary tumor location in CRC. A better outcome for left-sided colorectal cancer (CRC) compared with right-sided CRC has been reported. However, in those reports, the chemotherapy regimens always included molecularly-targeted agents. To the best of our knowledge, the impact of primary tumor location as a predictive factor in cytotoxic anti-cancer agent alone (FOLOX/FOLFIRI without molecularly-targeted agents) remains to be explained.

Aims and Methods: The purpose of this study was to clarify the impact of primary tumor location as a predictive factor in cytotoxic anti-cancer agent using CD-DST. Between Mar. 2008 and Apr. 2017, we obtained tumor specimens from 133 CRC patients (CC; n=87, Rectal Cancer; n=46) without preoperative chemother- apy. Written informed consent for measurement of individual chemosensitivity was obtained from all patients. Approval for the present study was obtained from the Tobu Chikuji Hospital Institutional Review Board (No: 02.03.29. #1).
CD-DST was performed and the growth inhibition rate (IR) was determined by incubation with 5-FU and l-OHP. The IR values under each condition and the relationship between the tumor side and the IR values were evaluated using linear regression analysis and t-test, respectively. Cancers present normal or distal of the splenic flexure were classified as right-side or left-side, respectively.

Results: There was a strong correlation between the IRs (%) of the FOLFOX and FOLFIRI regimens for right-sided vs left-sided tumors. In the FOLFOX regimen, the IRs (%) of right-sided and left-sided tumors were 57.4 ± 2.5 and 58.5 ± 1.8, respectively (p = 0.72). In the FOLFIRI regimen, the IRs (%) of right-sided and left-sided tumors were 67.0 ± 2.3 and 65.8 ± 1.9, respectively (p = 0.9).

Moreover, in 87 CT patients, there was also no significant difference in the IRs (%) of the FOLFOX and FOLFIRI regimens for right-sided vs left-sided tumors. In the FOLFIRI regimen, the IRs (%) of right-sided and left-sided tumors were 67.0 ± 2.3 and 69.1 ± 2.4, respectively (p = 0.53).

Of the 133 patients, 42 patients received palliative chemotherapy after surgery. From the 42 patients, the same results were also obtained.

Conclusion: In this study, there was no impact of primary tumor location in cytotoxic anti-cancer agent regimens for CRC. In contrast, as previously reported, a better outcome for left-sided CC compared with right-sided CC depended on one’s tumor biology, especially when using molecular-targeted agent regimens.

As such, our findings underscore the fact that molecularly-targeted agents rather than cytotoxic anti-cancer agents may result in a better outcome for left-sided tumors.

Introduction: Lynch syndrome carriers’ surveillance is performed through endoscopic examinations and with intervals of no more than 2 years. Colonoscopy allows direct visualization of the entire colon but requires bowel preparation, sedation, there is risk of intestinal perforation, it is time consuming and it has high associated costs. These are some of the reasons for which there is low surveillance acceptance among patients.

Aims and Methods: The aims of this work were to compare a specific faecal bacterial signature of sporadic colorectal cancer patients (CRC) and inflammatory bowel disease patients (IBD) with Lynch carriers and develop a non-invasive tool, hereby named RAID-LS, based on these bacterial signatures, which enabled the detection of neoplasia in Lynch population.

A cohort consisting of 66 Lynch syndrome carriers who underwent a surveillance colonoscopy were recruited. A second cohort consisting of control individuals was recruited through the regional CRC screening program or for presenting CRC compatible symptomatology. We performed the analysis of 9 CRC-specific bacterial markers (CRC1, 2, 3, 4, 5, 6, 7, 9, 10) and 4 associated to IBD (IBD1, 2, 3, 4) in stool samples. The RAID-LS was eventually defined using 3 of the analysed biomarkers.

Results: Comparison between those Lynch syndrome carriers who had had CRC and those with no CRC personal background did not show significant differences in the abundance of any of the analysed bacterial markers.

When Lynch with a normal colonoscopy (NC) were compared to control subjects with NC, non-advanced adenomas and advanced adenomas, significant differences were found in the abundance of 4 (CRC1, p = 0.014; CRC3, p < 0.001; CRC6, p < 0.001; CRC7, p = 0.03), 7 (CRC2, p = 0.043; CRC3, p < 0.001; CRC5, p < 0.001; CRC6, p < 0.001; IBD2, p = 0.013; IBD4, p = 0.003) and 9 bacterial markers (CRC2, p = 0.010; CRC3, p < 0.001; CRC5, p < 0.001; CRC6, p < 0.001; CRC7, p < 0.001; IBD2, p = 0.013; IBD2, p = 0.046; IBD3, p = 0.003; IBD4, p = 0.005), respectively. Interestingly, only CRC3 showed significant differences when NC Lynch were compared to control subjects with CRC (p = 0.034).

We designed the RAID-LS algorithm combining CRC1, CRC3 and IBD2 bacterial markers. This combination allowed the detection of neoplastic lesions in Lynch syndrome carriers with sensitivity, specificity, true and negative predictive values of 100%, 72%, 42% and 100%, respectively (AUC = 0.859, 95% CI (0.754-0.964)). These results led to a false-positive rate of only a 23%, reducing by 60% the number of colonoscopies.

Conclusion: Healthy Lynch syndrome carriers show a similar microbiota to that of patients with tumour lesions, suggesting that there is an inflammatory basal gut environment in Lynch similar to that of CRC. RAID-LS efficiently detects pre-neoplastic lesions in Lynch carriers. The use of this tool would suppose a breakthrough for Lynch carriers, who will significantly improve their quality of life by expanding the intervals between colonoscopic surveillance.

P0432 COMPARISON OF THREE LYMPH NODE STAGING SCHEMES FOR PREDICTING SURVIVAL IN PATIENTS WITH COLORECTAL CANCER: A LARGE POPULATION DATABASE AND CHINESE MULTICENTER VALIDATION

Q-W Zhang, C-H Zhang, X-B Li, Z-Z Ge
1Ren Ji Hospital Shanghai Jiao Tong University School Of Medicine, Division of Gastroenterology and Hepatology, Shanghai, China
2Shanghai Ninth People’s Hospital, Shanghai, China
3Ren Ji Hospital Shanghai Jiao Tong University School Of Medicine, Shanghai, China

Contact E-Mail Address: zhangqingweif@hotmail.com

Introduction: Several node staging schemes have been proposed for colorectal cancer (CRC) and multiple studies have been conducted to whether number-based scheme (pN), ratio-based scheme (rN) or log odds of positive lymph nodes scheme (LODDS) was associated with CRC survival. However, to the best of our knowledge, there was no study investigate which kind of node staging schemes predicted CRC survival to the best using predicting capacity and the optimal system remains controversial.

Aims and Methods: This study aims to compare 3 node staging schemes in predicting survival outcome in patients with colorectal cancer. Patients with CRC were identified from the Surveillance, Epidemiology, and End Results (SEER) database, and a Chinese multicenter cohort was used for independent validation. The prognostic performance of 3 node staging schemes predicting CRC cause-specific survival (CSS) was compared, involving pN, rN and LODDS. Prediction performance were assessed for overall survival using R2, discriminatory capacity using Harrell’s C statistic, time-dependent receiver operating characteristic (tdROC) at 1, 3, 5, 7, 10 year survival and clinical utility using decision curve analysis (DCA) at 1, 3, 5, 7, 10 year survival. Sensitivity analyses were performed when competing risk was considered or when overall survival (OS) was used. R2 and Harrell’s C statistic was assessed for each multivariate model after including sex, race, age, tumor location, T stage, M stage, grade, histology and size.

Comparison in predicting OS was also performed in Chinese multicenter cohort using R2, Harrell’s C statistic and tdROC.

Results: There were 240,886 patients in the SEER database and 1316 in the Chinese multicenter cohort. LODDS scheme performed better in overall performance R2 (LODDS vs. rN vs. pN: 19.4% vs. 17.6% vs. 9.4%), predictive accuracy (LODDS vs. Harrell’s C statistic (LODDS vs. rN vs. pN: 0.727 vs. 0.719 vs. 0.712) and ROC (LODDS vs. rN vs. pN: 1year: 74.4 vs. 76.1 vs. 77.3; 3year: 75.5 vs. 76.5 vs. 77.4; 1year: 74.9 vs. 75.6 vs. 76.4; 3year: 74.4 vs. 74.9 vs. 75.2; 1year: 73.6 vs. 73.9 vs. 73.9) than either pN or rN, for patients with colorectal cancer in SEER database. DCA also showed LODDS scheme had higher net benefit than either pN or rN (LODDS vs. rN vs. pN: 1year: 0.019 vs. 0.019 vs. 0.007; 3year: 0.116 vs. 0.118 vs. 0.052; 5year: 0.171 vs. 0.139 vs. 0.139; 7year: 0.200 vs. 0.184 vs. 0.184; 1year: 0.226 vs. 0.219 vs. 0.219) when threshold probability was set at 20%. Similar results could be attained in the sensitivity analysis, multivariate cox model and independent Chinese multicenter cohort.

Conclusion: LODDS performed better than rN, and pN in predicting CRC survival.

Disclosure: Nothing to disclose.

Abstract No: P0432: Overall prognostic performance of node staging schemes for colorectal cancer using different analytic strategy

Analysis R2 Harrell’s C index ROC at 1 year ROC at 3 year ROC at 5 year ROC at 7 year ROC at 10 year

Multivariate model
pN 0.214 0.754 (0.753-0.755) 80.7 80.5 79.5 78.4 77.4

LODDS 0.143 0.656 (0.630-0.682) 73.4 70.3 69.1 69.0 69.0 NA
A total of 237 patients with pT1 rectal cancer were enrolled. Median follow-up period was 57 months (range, 12–180 months). Group A, B, and C were 29, 169, and 39 cases. RR in group A, B, and C was 20.7% (6 cases), 4.0% (1 case), and 0.0% (0 case), respectively. In Group A, 3 cases developed local recurrence and the other 3 cases developed distant metastasis. In Group B, 2 cases developed local recurrence and the other 6 cases developed distant metastasis. RR in group A was significantly higher than group B and C (p = 0.001), 5-year DFS in group B (95.3%) and group C (96.3%) were significantly better comparing group A (70.8%) (A vs B, A vs C, p < 0.05). 5-year OS in group B (97.2%) and group C (96.2%) was also better comparing with group A (88.7%), however the difference was not significant among 3 groups. And, there were no significant differences between group B and C. DFS, OS, and DFS. Ionic Conclusion: Long-term outcomes of adj CRT after local resection for patients with high-risk pT1 rectal cancer were similar to those of surgical resection. Adj CRT may be a treatment option if patients with high risk pT1 rectal cancer reject additional surgery. Disclosure: Nothing to disclose

Introduction: We previously reported the risk for local recurrence was significantly lower with rectal cancer patients with cancer when treated with only endoscopic resection (ER) for pT1 colorectal cancer having high risk of lymph node metastasis. Especially, patients with high-risk pT1 rectal cancer should be recommended additional surgery after ER to prevent recurrence. However, the role of additional surgery with high-risk pT1 rectal cancer was impossible to be established due to additional surgery because of high invasiveness including permanent stomata. Recently, we have experimentally performed adjuvant chemoradiotherapy (adj CRT) for only patients who had rejected additional surgery after local resection including ER or transanal local excision for pT1 rectal cancer in the rectum.

Aims and Methods: Our aim is to clarify long-term outcomes of local resection followed by adj CRT for patients with high-risk pT1 rectal cancer. We retrospectively collected all data on patients with high-risk pT1 rectal cancer treated from January 2000 to December 2016 in our hospital. Patients were classified into 3 groups: patients undergoing only local resection (group A), patients undergoing initial or additional surgical resection with lymph node dissection (group B), and patients undergoing local resection after local resection for pT1 rectal cancer (group C). Adj CRT consisted of continuous infusion of 5-fluorouracil or oral administration of capecitabine, and concurrent radiation of 45 Gy in total. We assessed to compare the recurrence rate (RR), 5-year disease-free survival (DFS), and 5-year overall survival (OS) between each groups.

Results: A total of 237 patients with pT1 rectal cancer were enrolled. Median follow-up period was 57 months (range, 12–180 months). Group A, B, and C were 29, 169, and 39 cases. RR in group A, B, and C was 20.7% (6 cases), 4.0% (1 case), and 0.0% (0 case), respectively. In Group A, 3 cases developed local recurrence and the other 3 cases developed distant metastasis. In Group B, 2 cases developed local recurrence and the other 6 cases developed distant metastasis. RR in group A was significantly higher than group B and C (p = 0.001). 5-year DFS in group B (95.3%) and group C (96.3%) were significantly better comparing group A (70.8%) (A vs B, A vs C, p < 0.05). 5-year OS in group B (97.2%) and group C (96.2%) was also better comparing with group A (88.7%), however the difference was not significant among 3 groups. And, there were no significant differences between group B and C. DFS, OS, and DFS. Ionic Conclusion: Long-term outcomes of adj CRT after local resection for patients with high-risk pT1 rectal cancer were similar to those of surgical resection. Adj CRT may be a treatment option if patients with high risk pT1 rectal cancer reject additional surgery. Disclosure: Nothing to disclose

P0436 ALCOHOL CONSUMPTION IS ASSOCIATED WITH THE RISK OF DEVELOPING COLORECTAL NEOPLASIA: PROPENSITY MATCHING ANALYSIS
Y.J Yang, C.S Bang, G.H Baik
Hallym University College of Medicine, Chuncheon, Korea, Gastroenterology, Chuncheon, Korea (University of)

Contact E-Mail Address: outopiari@naver.com

Introduction: Despite the well-known association between alcohol consumption and colorectal neoplasms, the cumulative effect of alcohol consumption at the time of surveillance colonoscopy has not been investigated. Alcohol consumption after polypectomy is not included in the risk factors for the determination of the time interval of surveillance colonoscopy.

Aims and Methods: This study aimed to determine if alcohol consumption is associated with the development of CRN at the time of surveillance colonoscopy taking consideration of index colonoscopy findings and data on alcohol consumption. We prospectively identified 1,448 patients who underwent index and subsequent surveillance colonoscopy during the study period. The association between significant alcohol consumption (>30g/day, females >20g/day) and development of new CRN was examined. Moreover, significant alcohol consumption was a risk factor for CRN occurrence at the time of surveillance colonoscopy with marginal significance in male (aHR: 2.64, 95% CI: 0.93–7.52, p = 0.07). There was no association between significant alcohol consumption and overall CRN occurrence at the time of surveillance colonoscopy (aHR: 2.01, 95% CI: 1.14–3.52, p = 0.02). Furthermore, there is no association between significant alcohol consumption and development of advanced CRN on surveillance colonoscopy (aHR: 2.01, 95% CI: 1.14–3.52, p = 0.02). However, it was assumed that the risk of overall CRN occurrence, especially in patients in the normal or low-risk categories at index colonoscopy, was associated with significant alcohol consumption. Significant alcohol consumption was associated with the overall CRN occurrence at the time of surveillance colonoscopy in the normal (aHR: 1.90, 95% CI: 1.16–3.13, p = 0.01) and low-risk groups (aHR: 2.13, 95% CI: 0.98–4.62, p = 0.06). Moreover, significant alcohol consumption was a risk factor for CRN occurrence at the time of surveillance colonoscopy, suggesting that it is too low to safely exclude residual cancer. These biopsies should not be used to determine the value of this 1mm cut-off to predict local recurrence of cancer.

P0437 LONG-TERM OUTCOMES AFTER ENDOSCOPIC VERSUS SURGICAL TREATMENT OF T1 COLRECTAL CARCINOMA

H L Lee, Y.-S Cho, H.-H Lee, C.-H Lim, J Kim, B.-I Lee, M.-G Choi
Seoul St. Mary's Hospital, The Catholic University of Korea, Department of Internal Medicine, Seoul, South Korea (Republic of)

Contact E-Mail Address: lh.l.ee2002@hanmail.net

Introduction: The gold standard for treatment of T1 carcinoma used to be an oncological surgical resection including resection of draining lymph nodes. The number of endoscopic resections of T1 carcinoma will continue to increase in line with the increased detection. Increasing evidence showed that endoscopic resection is adequate for T1 carcinoma with a low risk for LMN. Long-term outcomes of patients with T1 colorectal cancer (CRC) treated by endoscopic resection (ER) or surgical resection have not been well established in Korea.

Aims and Methods: The aim of this study was to evaluate the long-term outcomes among patients with T1 CRC. This retrospective study included 386 patients with T1 CRC with initial endoscopy (n = 188) or surgery (n = 198) between 2000 and 2010 at the St. Mary's Hospital. Patients who did not meet the criteria including those with disease recurrence were excluded. The outcomes were compared in the Japanese Society for Cancer of the Colon and Rectum guidelines (negative resection margin, no lymphovascular invasion, submucosal invasion depth < 1000 μm, well/moderately differentiated adenocarcinoma, grade 3 tumor budding) were defined as 'low risk', and were subdivided into 4 groups: ER with low risk (Group A: 71 patients), ER with high risk (Group B: 117 patients), surgery with low risk (Group A: 65 patients), surgery with high risk (Group B: 133 patients).

Results: During follow-up period, local recurrence or distant metastasis was developed in 8 (1.8%) patients (Group A: 0, Group B: 4, Group C: 0, Group D: 4). 5-year recurrence free survival rate was significantly lower in Group B (Group A: 100%, Group B: 85.0%, Group C: 98.5%, Group D: 95.6%, p = 0.02). However, there was no statistically significant difference in the 5-year overall survival rate among treatment methods (Group A: 100%, Group B: 94.2, Group C: 98.5%, Group D: 98.1%, p = 0.23). Among patients (n = 285) who underwent surgery, lymph node metastasis (LNM) was observed in 33 (11.6%) patients. In the multivariate analysis, lymphatic invasion and depth of submucosal invasion were independent risk factors of LNM.

Conclusion: Endoscopic resection of T1 CRC in patients with low risk is safe. ER for T1 CRC did not worsen the clinical outcomes of patients who required additional surgical resection.

Disclosure: Nothing to disclose

P0438 QUALITY OF LIFE AND WORRY ABOUT CANCER RECURRANCE IN T1 COLRECTAL CANCER PATIENTS TREATED WITH ENDOSCOPIC OR SURGICAL TUMOUR RESECTION

Introduction: To optimise therapeutic decision-making in T1 colorectal cancer (T1 CRC) patients, it is important to elicit the patient’s perspective next to considering medical outcomes. Because empirical data on patient-reported impact of different treatment options are lacking, we evaluated patients’ quality of life, perceived time to recovery and worry about cancer recurrence after endoscopic or surgical treatment for T1 CRC.

Aims and Methods: In this cross-sectional study, we selected patients with histologically confirmed T1 CRC, who had participated in the Dutch Bowel Cancer Audit (ABK). These patients received endoscopic or surgical treatment between January 2014 and July 2017. Quality of life was measured using the EORTC QLQ-C30 and the EQ-SD-5L questionnaire. We used the Cancer Worry Scale to evaluate patients’ worry about cancer recurrence. A question on perceived time to recovery after treatment was also included in the set of questionnaires sent to the patient.

Results: Of all 119 eligible patients, 92.4% responded to the questionnaire (endoscopy group: 55/62, surgery group: 55/57). Compared to the surgery group, perceived time to recovery was on average 3 months faster in endoscopically treated patients after adjustment for confounders (p = 0.001). The 2 treatment groups did not show any significant difference in global quality of life, functioning domains as well as symptom severity. Moreover, patients in the endoscopy group did not report significantly more worries about cancer recurrence than those in the surgery group.

Conclusion: From the patient’s perspective, endoscopic treatment provides a quicker recovery than surgery, without provoking more cancer recurrence worries or any deterioration in quality of life. These results contributed to the shared therapeutic decision-making process of clinicians and T1 CRC patients.

3Hopital Nord - Assistance publique des hopitaux de Marseille, Marseille, France
4Hopital Aus-Marseille, Marseille, France
5Aix Marseille Université, Gastroenterology, Marseille, France

Contact E-Mail Address: charlotte.andrianjafy@gmail.com

Introduction: The aim of the study was to describe the results of 3-dimensional high-resolution anorectal manometry (3DHRAM) in a large cohort of patients with functional anorectal disorders.

Aims and Methods: In this single-centre retrospective study, all consecutive patients referred for investigation of faecal incontinence (FI) or dyssynergic defecation (DD) underwent 3DHRAM. The parameters analysed were usual manometric data, repartition of dyssynergic patterns, and the prevalence of a new ‘muscular subtype classification’ underlying dyssynergia, of anal sphincter defects and of pelvic floor disorders.

Results: Final analyses were performed in 1477 patients of mean age 54 ± 16 years, 825 were suffering from DD and 652 from FI. Among the patients, 86% met dyssynergia diagnostic criteria. Dyssynergic pattern II was the most frequently observed (56%) in women and in men suffering from FI, as well as in women with DD. Type I was the most frequently observed in men with DD (49%). Regarding the muscle type subgroups, combined puborectalis muscle involvement with external anal sphincter profile was the most frequently observed pattern. The global prevalence of rectal intussusception and of excessive peri-anal relaxation were 13% and 21%, respectively. The type III dyssynergic pattern was more frequently associated with pelvic floor disorders than other types (p < 0.001).

Conclusion: This large cohort study provides reference values of 3DHRAM in patients with functional anorectal disorders. Further studies will be necessary to assess the prevalence of pelvic floor disorders in healthy volunteers and to develop new scores and classifications including all of these new parameters.

Disclosure: VB, MB and CA have conflicts of interests. They previously have worked for Given Imaging as experts in order to teach 3DHRAM to other practitioners.

P0440 THREE-DIMENSIONAL HIGH-RESOLUTION ANORECTAL MANOMETRY CAN PREDICT RESPONSE TO BIOFEEDBACK THERAPY IN DEFECATION DISORDERS

C Andrianjafy, C Bazin, L Luciano, A Loundou, M Bouveri, V Vitton
1Centre hospitalo-universitaire de Nancy, Nancy, France
2Hopital Laxaner, Marseille, France
3Hopital Nord - Assistance publique des hopitaux de Marseille, Marseille, France
4Aix Marseille Université, Marseille, France
5Aix Marseille Université, Gastroenterology, Marseille, France

Contact E-Mail Address: charlotte.andrianjafy@gmail.com

Introduction: Biofeedback therapy (BT) is a simple and effective technique for managing outlet constipation and faecal incontinence. Several clinical factors are known to predict BT response, but a 50% failure rate persists. Better selection of BT responsive patients is required. We aimed to determine whether the defecation disorder type per high-resolution manometry (HRM) was predictive of BT response.

Aims and Methods: We analyzed clinical, manometric and ultrasound endoscopic data from patients who underwent BT in our department between January 2015 and December 2016. Patients were classified into 4 groups per the following defecation disorder classification criteria: rectal pressure > 40 mmHg and anal paradoxical contraction (type I); rectal pressure < 40 mmHg and anal paradoxical contraction (type II); rectal pressure > 40 mmHg and incomplete anal relaxation (type III); and rectal pressure < 40 mmHg and incomplete anal relaxation (type IV). An experienced single operator conducted 10 weekly 20-minute sessions. Efficacy was evaluated with the visual analog scale.

Results: Of 92 patients, 47 (50.5%) responded to BT. Type IV and type II defecation disorders were predictive of success (p = 0.03) OR = 5.93 [1.02; 24.92] and failure (p = 0.05) OR = 0.41 [0.17; 0.99], respectively. The KESS score severity before BT (p = 0.03) OR = 0.9 [0.81; 0.99] was also predictive of failure.

Conclusion: The manometry types identified according to the defecation disorder classification criteria were predictive of BT response. Our data confirm the role of 3-dimensional HRM in the therapeutic management of anorectal functional disorders.

Disclosure: VB, MB and CA have conflicts of interests. They previously have worked for Medtronic as experts in order to teach 3DHRAM to other practitioners.
P0441 WHOLE AND REGIONAL ASSESSMENT OF CONTRACTILE TEMPERATURE AND PH PROFILE IN PATIENTS WITH FUNCTIONAL CONSTIPATION, IRRRITABLE BOWEL SYNDROME WITH CONSTIPATION AND HEALTHY VOLUNTEERS USING WIRELESS MOTILITY CAPSULE

Introduction: Constipation is a very common disorder with a wide spectrum, from functional constipation (FC) to irritable bowel syndrome with constipation (IBS-C). There are similarities and differences between FC and IBS-C including changes in gut microbiota compared to healthy volunteers (HV). The wireless motility capsule (WMC) incorporates measurements of pressure, temperature and pH along the gastrointestinal (GI) tract. Whole and regional transit times, pressure pattern and pH have been described in several populations.

Methods: This is a prospective study conducted at 2 GI Motility Labs, in the INCNMSZ and IMUBU-V. We included patients fulfilling Rome III criteria for FC and IBS-C. HV were asymptomatic, no major comorbidities, no previous GI surgery. After a 12-hour fast, WMC was administered without having consumed antibiotics in the previous month, no bowel preparation and no fiber supplement administered for 7 days before WMC. Subjects were instructed to wear a receiver and a diary until WMC was expelled or for up to 120 hrs. Whole and regional transit time, pressure pattern and pH profile were evaluated. For detailed analysis, small bowel (SB) and colon were divided into quartiles. The data were analyzed using specialized software (GIMS data viewer, Buffalo, NY). The variables are summarized with medians, frequencies and percentages. Non-parametric tests were used for comparisons.

Results: 52 subjects were included, 17 HV, median age 39 yo (25–54, 25th–75th), IBS-C 27 (21–34), FC 23 (21–27). 8 IBS-C, median age 29.5 yo (24–41.5), BMI 25.9 kg/m² (21.2–28.7) and 27 FC median age, 41 yo (31–56), BMI 26.8 kg/m² (23.5–32.9). There was no difference in age distribution (p = 0.35) or BMI (p = 0.52). No changes were shown in whole and regional transit times and pressure pattern between groups (p > 0.05) (Table). FC had a lower SB pH profile, 6.66 (6.42–6.88, p = 0.039) compared to HV 6.87 (6.7–7.03) and IBS-C 7.03 (6.97–7.10) (Figure). Similarly, at ileum (distal quartile in SB), pH was lower in FC 7.18 (7.08–7.42, p = 0.023) vs HV 7.44 (7.19–7.66) and IBS-C 7.54 (7.47–7.66). At cecum (1st quartile for SB); pH had lower in FC 5.72 (5.4–6.22) compared to IBS-C 6.31 (6.14–6.82; p = 0.024) but not different to HV.

Conclusion: FC presents a more acidic profile in the SB, ileum and cecum. This leads to the hypothesis that changes in pH may be due to differences in microbiota composition between study populations. It is necessary to evaluate these findings when comparing microbiota with intraluminal pH and symptom profile.

Disclosure: Nothing to disclose.

P0442 LONG-TERM LINK BETWEEN THE SEVERITY OF FAECAL INCONTINENCE AND THE EXTENT OF THE OBSTETRICAL ANAL SPHINCTER DISRUPTION

Introduction: Anal sphincter disruption, mainly from obstetrical origin, is frequent in patients suffering from fecal incontinence (FI). However, the link between the extent of the disruption and the severity of FI is not clear according to the time between the anal sphincter disruption and the apparition of FI. Our main objective was to assess, in the long term, the link between the anal sphincter disruption and the severity of FI.

Aims and Methods: In this retrospective study, all patients referred to our center for investigation of FI including an endo-anal ultrasonography (EUS) and a 3D manometric data, the voluntary contraction was lower in patients with EAS disruption in 8.4%, both IAS and EAS disruption in 60%. Considering manometric data, the voluntary contraction was lower in patients with EAS disruption. In the long term, this role is reduced due to the multifactorial nature of FI.

Disclosure: WV and CA have conflicts of interest. They previously have worked for Asta in astaxanthin experts in order to teach 3-dimensional high-resolution manometry to other practitioners.

P0443 POLYETHYLENE GLYCOL 3350 PLUS ELECTROLYTES FOR CHRONIC CONSTIPATION: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED MEDIUM-TERM STUDY WITH AN EXTENSIONAL 52 WEEKS OPEN-LABEL, LONG-TERM STUDY

Nakajima, A; Kimbo, A; Ota, Y; Kinoshita

Introduction: Although polyethylene glycol 3350 plus electrolytes (PEG3350+E) is the most popular osmotic laxative in Europe, prospective long term (over 6 months) safety and efficacy clinical data has not been available to date. In Japan, the current standard cure of chronic constipation is magnesium oxide. PEG3350+E has not previously been used as treatment for chronic constipation.

Aims and Methods: We aimed to determine the efficacy and safety of PEG3350+E for the treatment of chronic constipation with an extensional long term study in Japan. We report a Phase 3 trial; a randomized, double-blind, placebo-controlled medium-term study (Confirmatory phase) with an extensional open-label, long-term (52 weeks) study (Extensional phase) in patients with chronic constipation who satisfied Rome III criteria for functional constipation. In the Confirmatory phase, 156 patients were randomized to receive PEG3350+E (80) or placebo (76) orally for 2 weeks. In the Extensional phase, 153 patients moved from the Confirmatory phase and received PEG3350+E orally. Starting dose was 13.7g/day dissolved in 125mL of water; dose titration was allowed in both phases within the range of 13.7–41.4g/day, according to the patient’s bowel condition. We monitored bowel function (including number of bowel movements, stool consistency) and adverse events. The primary end point of the Confirmatory phase was the increase from baseline (last week of run-in period: Week -1) in spontaneous bowel movements (SBM) per week during Week 2 of treatment. Secondary endpoints included frequency of complete spontaneous bowel movements (CSBMs), proportion of responders (defined as 3 or more SBM/CSBM per week with an increase from baseline of at least 1 SBM/CSBM per week), the median day to first SBM, stool consistency.

Results: In the Confirmatory phase, the difference from baseline in frequency of SBMs in Week 2 was significantly increased with PEG3350+E (4.3 ± 2.9 [Mean ± SD]) compared with placebo (1.6 ± 2.0, p < 0.001). Similarly, the frequency of CSBMs and proportion of responders were significantly improved with PEG3350+E compared to placebo.

In the Extensional phase, PEG3350+E showed sustained improvement in bowel function. The difference from baseline in frequency of SBMs in Week 1 and Week 2 were 2.98 ± 2.27 and 4.34 ± 2.89 respectively. Thus, it showed an increasing trend until Week 2 and remained stable at 3.89–4.82 times from Week 2 through Week 52. The frequency of SBMs from Week 1 to Week 52 was significantly increased compared with baseline. The SBM proportion of responders was 78.4% (95% CI: 71.26%–84.21%) in Week 1 and remained stable at 78.4%–94.0% from Week 1 to Week 52. In the Confirmatory phase, the incidence of adverse events (AEs) of placebo and PEG3350+E were 19.7% (15/76 patients) and 20.0% (16/80 patients) in the PEG3350+E group, respectively. The incidence of adverse drug reactions (ADRs) of placebo and PEG3350+E were 5.3% (4/76 patients) and 7.5% (6/80 patients) respectively.

In the whole phase 3 trial, the incidence of AEs was 78.8 % (123/156 patients) and the incidence of ADRs was 21.2 % (33/156 patients). The most common ADRs were gastrointestinal disorders (abdominal pain: 4.5%, diarrhea: 3.8%, nausea: 3.2% and abdominal distension: 2.6%). The incidence of AEs did not increase through the whole phase 3 trial.

Conclusion: PEG3350+E resolves constipation compared to placebo in the medium term, is well tolerated and improves bowel functions when administered for 52 weeks in Japanese patients with chronic constipation.

**Introduction:** Patients with fecal incontinence (FI) who are refractory to Loperamide and biofeedback may respond to neuremodulation. Previous data suggests a possible benefit of Cholestyramine, an anion exchange resin, binds to bile in the gastrointestinal tract, for FI management. We report a single center experience of Cholestyramine in the treatment of FI.

**Aims and Methods:** We report 44 patients with FI refractory to lifestyle modifications, Loperamide and biofeedback therapy. All patients had organic disorders excluded by serology and endoscopy, and also had intact anal sphincters on endoanal ultrasound. Group A received Cholestyramine (median dose 4.9g per day) along with Percutaneous tibial nerve stimulation (PTNS) for 12 weeks and Group B received PTNS alone. Bristol stool form scale (BSFS), weekly incontinence episodes, weekly stool frequency, median St Mark’s faecal incontinence score and days per week with abdominal pain were assessed at baseline and 12 weeks after therapy. SeHCAT studies were undertaken in some patients during PTNS.

**Results:** Data is shown in the Table with group A patients showing greater improvement in stool form, bowel frequency, episodes of incontinence and incontinence score compared to Group B. Only Group A patients had reduced abdominal pain. A responder analysis (>50% episodes reduction) was greater in Group A than B (73% vs 48%).

In total, 26 patients underwent SeHCAT testing, 13 in each group: in Group A 7/13 were of whom 6 responded to cholestyramine + PTNS, in Group B 5/13 were positive, none of whom responded to PTNS alone.

**Conclusion:** Cholestyramine is efficient adjunctive therapy to PTNS for FI management. A positive SeHCAT was seen in 46% of patients, and associated with an excellent response to Cholestyramine.

**Disclosure:** Nothing to disclose.

Contact E-Mail Address: alissa.beath@mq.edu.au

**Introduction:** Anorectal biofeedback (BF) therapy has established efficacy for both fecal incontinence and dysentergic defecation. The BF program involves education and advice on toileting behaviour and positioning, diarrheagusting, manometric-based biofeedback aimed at normalising anorectal physiology, sensory retraining and balloon expulsion retraining. In addition to pre-treatment clinical state [1], some psychological characteristics of patients have shown to predict BF efficacy [2]. Although psychological mechanisms must be involved in this learning process, there is little information on the psychological changes that occur through anorectal BF.

**Aims and Methods:** Our aims were to determine (1) what psychological traits change as a result of BF, and (2) whether changes in psychological traits correlate with changes in patient symptoms and quality of life, in order to better understand their role in treatment efficacy. 67 patients (M longstanding = 57, SD = 17, 93% female) presenting to the Neurogastroenterology Unit at the Royal North Shore Hospital (Sydney, Australia) with fecal incontinence (FI) (n = 39) or dysentergic defecation (n = 28) underwent a 6-visit instrumental anorectal BF program. Measures of executive function, cognitive flexibility, perceived stress, emotion regulation and self-efficacy were recorded prior to and at the end of the program. Patient reported outcomes were symptom severity (Fecal Incontinence Severity Index and Constipation Score) and quality of life (Fecal Incontinence QOL and Patient Assessment of Constipation QOL) for FI and dysentergic defecation patients as appropriate. Spearman’s correlations above 0.3 were considered clinically meaningful (and bolded in the Table).

**Results:** Patients’ perceived stress, executive function, cognitive flexibility, self-efficacy, and adaptive health-focused emotion regulation significantly improved throughout BF (all ΔZ≤2.13, all ps ≤ 0.05). Change in psychological traits correlated more strongly with changes in QoL, as opposed to symptom severity (see Table). Improvement in constipation QoL was moderately correlated with greater decrease in stress and executive function impairment; improvement in FI QoL correlated with greater reduction in self-blame and catastrophizing, and increases in cognitive flexibility and self-efficacy.

**Conclusion:** Psychological traits of emotion regulation, cognitive functioning and stress improve through BF and correlate with improvements in PRO. While we cannot conclude causal direction of the relationships, our results open the possibility of potential mechanisms in BF efficacy, with potentially different mechanisms for dysentergic defecation and FI.

Introduction: Treatment of chronic idiopathic constipation is empiric, based on step-wise approach. Long-term conservative management (lifestyle advice and laxatives) do not relieve symptoms, secondary approaches with prokinetic or secretagogues are used before considering hospital-based care (biofeedback, psychosocial support, transanal irrigation (TAI), surgery). Nevertheless, patients are often unsatisfied with care and fail to progress to adequate levels of therapy. The 3-point Failure to Provide Adequate Relief (F-PR) scale was developed to facilitate the recognition of when to move from each step to the next. The aim of this research was to validate F-PR in a tertiary clinical setting.

Results: A total of 403 consultations were accomplished, in 200 of which clinical assessment identified inadequate relief with current therapy (laxatives 81 patients, enemas 22 patients, prucalopride 42 patients, lubiprostone 12 patients, transanal irrigation 20 patients, biofeedback 97 patients, surgery 3 patients or combination 127 patients). Neither duration nor type of treatment was correlated with relief. A total of 403 consultations of the F-PR had >96% but poor sensitivity (15-67%). Cumulatively, none of the subjects with 4 or more of 5 positive responses on the F-PR had adequate relief with their current treatment.

Conclusion: We have shown that the F-PR has excellent specificity, suggesting it is a useful confirmatory test to confirm a clinical suspicion of inadequate relief. Good sensitivity is only seen when there are no positive F-PR replies implying the F-PR is only of screening value when there is high likelihood of treatment satisfaction. As such, the F-PR may have a role in confirming efficacy of treatments in future stepwise therapy for chronic constipation.

Disclosure: Nothing to disclose

P0448 RISK OF COLONIC DIVERTICULAR REBLEEDING ACCORDING TO ENDOSCOPIC APPEARANCE
K Kawanishi, M Kitano
Wakayama Medical University, Second Department Of Internal Medicine, Wakayama City, Japan

Contact E-Mail Address: amurosyaya218@yahoo.co.jp

Introduction: Re-occurrence of bleeding (rebleeding) of colonic diverticula after endoscopic hemostasis is a clinical problem.

Aims and Methods: This study aimed to examine whether endoscopic visibility of colonic diverticula and bleeding affects the rebleeding after endoscopic hemostasis. We performed a retrospective review of endoscopic images and medical charts of patients with colonic diverticular bleeding who underwent endoscopic hemostasis. Endoscopic visibility was classified into 2 types according to visibility of the source of bleeding: source invisibility due to bleeding or attached hematin (type 1), or endoscopically visible responsive vessels (type 2). Rebleeding rates within 1 year after initial hemostasis were examined.

Results: Of 93 patients with successful endoscopic hemostasis, 38 (41%) showed type 1 visibility, while the remaining presented type 2. All patients received hemostasis with clipping, rebleeding developed in 20 patients (22%). Type 1 visibility was more likely to be observed in patients with rebleeding (65% vs. 34%, p = 0.06). Kaplan-Meier curve showed the cumulative incidence of rebleeding was significantly higher in patients with type 1 visibility than those with type 2 visibility (p = 0.0033, log-rank test)

Conclusion: Hemostasis by clipping for colonic diverticular bleeding without definite observation of the source of bleeding may not be sufficiently effective. Other hemostatic methods, including band ligation, should be considered when the source of bleeding is unclear.

Disclosure: Nothing to disclose

Introduction: A validated endoscopic classification of Diverticular disease (DD) of the Colon, called DICA (Diverticular Inflammation and Complication Assessment), is currently available.

Aims and Methods: Our aim was to assess the agreement on this classification among an endoscopists community setting.

The DICA score for DD resulted in the sum of the scores for extent of diverticulosis, number of diverticula per district, presence and type of inflammation, and presence and type of complications: DICA 1 (upto 3 points); DICA 2 (4 from 7 points); DICA 3 (over 7 points). A total of 35 endoscopists,
subdivided between expert (31 raters, namely endoscopists using this classification) and non-expert (14 raters, not expert about DICA classification (24 raters)), independently scored a set of DD endoscopic videos using DICA classification.

The percentages of overall agreement on DICA score and a free-marginal multirater kappa (κ) coefficient were reported as statistical measures of inter-rater agreement.

Results: 1375 visualizations were performed. The overall agreement levels among the total group of raters were: DICA 1, 70.2%; DICA 2, 70.5%; DICA 3, 81.3%. The inter-rater agreement between the 55 evaluators varied as follows: DICA 1, free-marginal κ = 0.553; DICA 2, free-marginal κ = 0.558; DICA 3, free-marginal κ = 0.719. The overall agreement levels among the expert group of raters were: DICA 1, 78.8%; DICA 2, 80.2%; DICA 3, 88.5%. The inter-rater agreement between the 31 expert evaluators varied as follows: DICA 1, free-marginal κ = 0.682; DICA 2, free-marginal κ = 0.712; DICA 3, free-marginal κ = 0.828

Conclusion: DICA score is a simple, reproducible, and easy-to-use endoscopic scoring system for diverticular disease of the colon. The inter-rater agreement in this study was strong with a significant improvement in the expert subgroup of raters.

Disclosure: Nothing to disclose.

P0450 LONG-TERM EFFICACY OF RIFAXIMIN IN MANAGING SYMPTOMATIC UNCOMPLICATED DIVERTICULAR DISEASE OF THE COLON

Introduction: Symptomatic Uncomplicated Diverticular Disease (SUDD) affects about 20% of patients having diverticular disease. However, there is no consensus about the best treatment in treating this disease and in preventing the disease’s complications. Rifaximin, a not absorbable antibiotic, is currently advised as effective treatment in controlling symptoms and in preventing complications, but no long-term data are available.

Aims and Methods: Our aim was to assess the outcome of a cohort of SUDD patients treated with rifaximin during a retrospective follow-up study. The study group (group A) included 346 SUDD patients with a median (range) age of 61(49–83) years, of whom 216 (62.4%) were females. Patients were treated with rifaximin 800 mg/day for 7 days/month. The control group (group B) included 470 patients SUDD taking spasmodics when needed, with a median (range) age of 59 (47–81) years, of whom 288 (61.5%) were females. Diagnosis of SUDD was performed by colonoscopy and by clinical accepted criteria. Follow-up was for a period of 12 months or whenever patients considered necessary. At each control visit, symptoms were assessed by the Global Symptomatic Score (GSS), assessing 4 main variables (left lower abdominal pain, bloating, diarrhea, constipation) graded as 0 = no symptom; 1 = mild, symptoms easily tolerated; 2 = moderate, symptoms sufficient to cause interference with usual daily activities; and 3 = severe, incapacitating symptoms with inability to perform normal activities).

Results: At baseline global symptomatic score (interquartile range) was 7 (5–8) in the study group and 6 (4–8) in the control group (p = 0.243). Either abdominal pain, or bloating or bowel alteration were significantly reduced in the study group with respect to the control group. The number of visit/patient/year were 2.4 patient/year in group A and 4.2 patients/year in group B (p = 0.02). Acute diverticulitis occurred in 9 patients (2.6%) in group A and in 21 patients (4.6%) in group B (p = 0.01). Surgery due to complication of the disease occurred in 4 patients (1.16%) in group A and 9 (1.91%) in group B (p = 0.06). Deaths due to disease were 0 in group A and 2 (0.42%) in group B (p = 0.03).

Conclusion: Rifaximin is effective in the symptomatic relief of symptomatic uncomplicated diverticular disease of the colon. In particular, symptomatic relief was due to a significant reduction in bloating and bowel alteration symptoms. Finally, rifaximin seems to be also effective in reducing the risk of disease’s complications.

Disclosure: Nothing to disclose.

P0451 DEMOGRAPHIC AND CLINICAL FACTORS ASSOCIATED WITH TREATMENT USE IN PATIENTS WITH DIVERTICULAR DISEASE: RESULTS FROM THE ITALIAN NATIONAL REGISTRY REMAD

C Cremon1, M Carabotti2, R Cuomo3, F Pace4, P Andreozzi5, B Annibale6, G Barbera7

Introduction: Although diverticular disease is an extremely common condition, its effective treatment represents a difficult task in daily clinical practice. We have used the Italian national ‘Registro Malattia Diverticolare’ (REMAD) registry, an ongoing 5-year prospective, observational, multicenter cohort study in 1206 consecutive patients with diverticular disease, to assess the prevalence of treatment use in the different clinical entities of this disorder and the demographic and clinical factors associated.

Aims and Methods: At the entry in the REMAD registry, patients were categorized in subgroups according to different clinical entities (diverticulitis, symptomatic uncomplicated diverticular disease (S UDD), previous diverticular (PD)). Demographic, clinical and lifestyle factors and quality of life were registered (Carabotti et al., UEG Journal 2018 in press) as well as the use of 1 or more treatments for diverticular disease (including poorly absorbed antibiotics, like rifaximin, mesalazine, probiotics, prebiotics, fibers, and antisepsimeds) in the last year. Logistic regression analysis was used to assess the association between demographic and clinical factors with treatment assumption.

Results: Of the 1206 subjects included in the study have taken at least 1 treatment for diverticular disease in the last year. Of these subjects, 166 belong to diverticulosis group (a total of 702 subjects with diverticulosis, 23.6%), 165 to SUDD group (of a total of 295 subjects with SUDD, 55.9%), and 169 to PD group (of a total of 209 subjects with PD, 80.9%) (p = 0.0001 for all). In both groups, poorly absorbed antibiotics, particularly rifaximin, were the most common treatment, accounting for 87.3% in diverticulosis, 84.8% in SUDD and 75.7% in PD. In a multivariate analysis, the following factors resulted to be significantly associated with treatment use: female gender (OR = 1.6; 95% CI, 1.1–2.2), family history of colon diverticulosis (OR = 1.5; 95% CI, 1.1–2.1), gastrointestinal comorbidity (OR = 1.9; 95% CI, 1.4–2.5) and impairment of quality of life, particularly the physical component summary (PCS) score (OR = 1.6; 95% CI, 1.2–2.2). Interestingly, older age (OR = 2.04; 95% CI, 1.1–3.7) and gastrointestinal comorbidity (OR = 2.1; 95% CI, 1.4–3.2) were the most relevant factors associated with the use of treatments in diverticulosis, while first-degree family history for colon cancer (OR = 2.4; 95% CI, 1.0–5.7) and for diverticulosis (OR = 2.5; 95% CI, 1.1–4.9), the presence of gastrointestinal comorbidity (OR = 2.3; 95% CI, 1.3–4.3) and the impairment of PCS score (OR = 2.2; 95% CI, 1.2–4.2) were significantly associated with treatment use in SUDD.

Conclusion: Pharmacological approaches targeting enteric bacteria (with poorly absorbed antibiotics, like rifaximin) are the most commonly used treatments for diverticular disease, due to their ability of controlling symptoms and also preventing complications. In addition, this nationwide registry study identified different demographic and clinical factors associated with the use of pharmacological approaches in the distinct clinical entities of diverticular disease. The optimal regimen of therapy must be established in ad hoc studies. ClinicalTrial.gov Identifier: NCT03325829.

Contact E-Mail Address: d.caroli@libero.it

Introduction: Diverticular disease (DD) of the colon represents a common clinical condition affecting with high rate the population in developed countries. Several epidemiological studies have clearly shown that in the last decades the rates of hospital admissions for Acute Colon Diverticulitis (ACD), the most important complication of DD, is progressively increased.

Aims and Methods: Describe the Hospitalization trend for ACD in Veneto region (North East Italy), including in-hospital mortality, and evaluate the impact of specialist admission hospital units as Gastroenterologic (GE) units.

Data were obtained from the Veneto Region anonymous Hospital Discharge data from 2000 to 2017, in which diverticulitis of colon [ICD-9-CM code 562.11 and 562.13 (diverticulitis with and without mention of haemorrhage) was the primary diagnosis.

Standardized Hospitalization Rate (SHR) per 5-year group (ref. pop. Veneto 2009) was calculated and expressed per 100,000 population.

To evaluate the impact of admission hospital units on the outcome of ACD management we analyzed in-hospital mortality, need for surgery (NFS) and lenght of stay (LOS).

Disclosure: Nothing to disclose.
significantly showed an important increase from 0.37 to 0.98 (p

Through the years the NFS rate was stable with an increase of mortality.

Women showed an higher prevalence of hospitalization compared to men (OR: 1.34; 95% CI: 1.27–1.32; p < 0.001).

Conclusion: It appear that ACD is an emerging health-care problem related to the rising of age.

4Lithuanian University of Health Sciences, Department of Surgery, Kaunas, Lithuania

Introduction: Human papillomavirus-associated anal intraepithelial neoplasia (AIN) is a precursor of invasive anal carcinoma. High-resolution anoscopy (HRA) is recommended as a screening tool for AIN (1). However, the diagnostic accuracy of this method is unclear. In contrast, anal mapping biopsies (AMB) are not widely performed and are not included in the current guidelines.

Aims and Methods: We aimed to evaluate HRA as a screening tool for AIN in comparison to anal mapping biopsies as the gold standard.

Results: 29 patients (20 male, 9 female) with anal mapping were analysed during 2 years. Of the 20 male patients, 11 were HIV positive and 14 practiced men sex with men (MSM). All women were HIV negative. HRA identified 23 lesions suspicious for AIN. 22 lesions (96%) were histologically confirmed as AIN.

Conclusion: This study shows that, although most AIN are detected with HRA, they are considered prior to local therapy, at least in high-risk patients with positive results in the HRA study.

Disclosure: Grant by Olympus, comparative study HRA vs. endoscopy for AIN diagnostics

Introduction: The diagnosis of Hirschprung’s disease (HD) relies on anorectal manometry, barium enema and rectal biopsy. The role of endoscopic biopsy is not well-known for the diagnosis of HD in children.

Aims and Methods: In this study, we evaluated the safety and adequacy of biopsies procured by endoscopic mucosal resection (EMR) for the diagnosis of HD. All the children with suspected HD underwent anorectal manometry and barium enema. Children with absence of recto-anal inhibitory reflex and / or radiological lesions procured by endoscopic mucosal resection (EMR) for the diagnosis of HD.

Aims and Methods: Prospective (2016–2018) randomized non-blinded sequential trial with four interventions (IH).

Comparative study on the efficacy and safety of 4 instrumental modalities for the screening of anal carcinoma in HIV infected patients. High-definition imaging with the BLI technology also allows for identification of vascular patterns, which might help to characterize dysplastic anal lesions and might therefore allow for more targeted diagnosis and treatment.

Disclosure: Nothing to disclose

PO456  HEMORROIDETQ STUDY: PROSPECTIVE EVALUATION OF FOUR NON-SURGICAL INTRAMURAL MODALITIES FOR THE TREATMENT OF PROLAPSED HEMORRHOIDAL DISEASE

Introduction: Persistent symptomatic hemorrhoidal disease after general counsel- measures requires instrumental intervention. The benefit of the association of phlebotonics is uncertain.

Aims and Methods: Comparative study on the efficacy and safety of 4 instrumental non-surgical modalities for treatment of prolapsed internal hemorrhoids (IH).

Prospective (2016–2018) randomized non-blinded sequential trial with four interventions: Rubber band ligation (B) or Sclerotherapy with Foam Polidocanol (PLD) vs. Ligature + phlebotonics (B+P) vs. PLD + P. Inclusion of adult patients with IH (grade II-III) diagnosis with no previous instrumental treat- ment, after signed written consent. Demographic and clinical characterization. Assessment of outcomes: Safety (adverse events after intervention); efficacy (complete, partial or absent response) at week 4–8 (short-term) and weeks 12–24 and 44–52 (long-term). Intervention if indicated, at the same timepoints.

Statistics: One-way ANOVA, Welch and Levene test; chi-square.

Results: 68 patients were included (37 males, mean age 54 ±12.8 years) and distributed among the 4 treatment groups (19 vs.19 vs.17 vs.13), adjusted for age (p=0.92) and gender (p=0.86).

Short-term analysis - all patients were evaluated for this analysis. 3 cases of self- limited pain only, were documented. Efficacy was superior for B group [no case of lack of response and 12/19 cases of complete response (p=0.006)].

Long-term analysis - 46 patients were assessed (5 dropouts, 17 still incomplete follow-up). 100% and 43% of re-interventions were performed on the 2nd and 3rd timepoints without reported adverse events. In this long-term evaluation there is no difference between the treatment modality and the efficacy, time made the outcomes similar between treatment groups: The efficacy of each treatment is provided in 75% complete response and 25% partial response, with numerical superiority for the PLD + P group (87.5% and 12.5%, respectively).

Conclusion: Non-surgical instrumental IH therapy is safe and globally effective. B showed to have superior efficacy at week 4 to 8, after a single intervention. Efficacy over time and after re-interventions is similar for B and PLD. Combined PLD + P therapy seems to enhance sustained efficacy over time.

Introduction: Human immunodeficiency virus (HIV) infection contributes to the occurrence of anal cancer in men who have sex with men (MSM), leading to a 30–100 fold higher anal carcinoma incidence in this patient group. Therefore convenient screening tools are mandatory to identify anal intraepithelial neoplasia (AIN) at early stages, which allow an early curative intervention.

Aims and Methods: In this pilot study we screened for anal carcinoma in HIV positive MSM, receiving stable antiretroviral therapy. Endoscopic high-intensity contrast imaging (HIC) and the most recently introduced Blue Light Imaging (BLI) with optical magnification were applied during high-resolution anoscopy. The HIC/BLI equipped endoscope was advanced into the anal region of interest via a pro-inserted standard rectoscope. Conventional imaging in combination with time-em, -enhancement, and swaps as well as directed biopsies served as refer- ence methods to identify AIN.

Results: Following preliminary inclusion of consecutive HIV patients, median (range) age 49.5 (37–61) years, CD4+ 363 (295–1076) cells/µl and HIV- RNA 10 (4–34) copies/ml, we were able to identify 1 patient with condyoma acuminata and low-grade AIN. HIC/BLI as well as aceto-enhancement both resulted in consistent findings and lead to the diagnosis of AIN. In addition more superficial HIC/BLI revealed superficial vascular patterns that was seen in the identified AIN and condyloma lesions. In contrast, anal swaps and cytology, showing inconclusive results (PAP Iib) in 20% (1/5) and normal cytology in 80% (4/5), were not able to identify AIN in these patients.

Conclusion: HIC/BLI enhanced anoscopy provides an additional time-sparring method for the screening of anal carcinoma in HIV infected patients. High-definition imaging with the BLI technology also allows for identification of vascular patterns, which might help to characterize dysplastic anal lesions and might therefore allow for more targeted diagnosis and treatment.

In:vestigators assessed oral Trisulphate Solution (OTS) is a low-volume bowel cleansing solution administered as 2 x 500 ml saline sulphate solution followed by 2 x 1 l water or clear liquids (for hydration). The aim of this study was to: assess misuse (defined as non-compliance with hydration); describe the safety profile overall and in case of misuse; and identify any immediate/acute adverse events (AEs) in special populations (the elderly and patients at risk of electrolyte shifts).

Aims and Methods: This was a prospective, non-interventional, multicentre, European Post Authorisation Safety Study (PASS) in patients receiving OTS for colonoscopy. The PASS was conducted in patients at risk of electrolyte shifts. The European Post Authorisation Safety Study (PASS) in patients receiving OTS for colonoscopy. The PASS was conducted in patients at risk of electrolyte shifts. The study was conducted in: Germany, the Netherlands and Poland. 1206 patients took OTS and provided 1048/1196 patients (87.6%). 329 patients (27.3%) experienced 758 related treat- ments in compliance. Reported colon cleansing level was excellent-to-good in 96.8%. Subgroup analyses (age, gender, dosing regimen) revealed no differ- ences in compliance. No AEs suggestive of dehydration were reported in 1048/1196 patients (87.6%). 329 patients (27.3%) experienced 758 related treat- ments in compliance. Reported colon cleansing level was excellent-to-good in 96.8%. Subgroup analyses (age, gender, dosing regimen) revealed no differ- ences in compliance. No AEs suggestive of dehydration were
noted in non-compliant patients. No acute AEIs were observed in special popula-
tions. TEAEs did not differ in nature and intensity from the known safety profile overall and in special populations.

**Conclusion:** In this non-interventional study, treatment compliance to hydration guidelines was excellent or good in 94.5% of patients. The safety profile of OTS was good and similar to previous reports overall and in special populations.

**P0459 OPTIMAL TIMING OF ADDING SIMETHICONE FOR BETTER BOWEL PREPARATION USING POLYETHYLENE GLYCOL PLUS ASCORBIC ACID: A DOUBLE-BLIND RANDOMIZED TRIAL

H Kim1, H.J. Goong2, B.M. Ko3, Y Jung4, S.R. Jeon5, H.G. Kim6, J.-O. Kim7, M.S. Lee

1 SoonChunHyang Bucheon Hospital, Internal Medicine, Digestive Disease Center and Research Institute, Bucheon, Korea (Republic of) 2 SoonChunHyang University School of Medicine, Digestive Disease Center and Research Institute, Department of Internal medicine, Bucheon and Seoul, Korea (Republic of) 3 SoonChunHyang University College of Medicine, Bucheon, Korea (Republic of) 4 SoonChunHyang University Hospital, Internal Medicine, Cheonan, Korea (Republic of) 5 Institute of Digestive Research, SoonChunHyang University College of Medicine, Department of Internal medicine, Seoul, Korea (Republic of) 6 SoonChunHyang University College of Medicine, Institute for Digestive Disease Research, Bucheon, Korea (Republic of) 7 SoonChunHyang University Hospital, Digestive Disease Center, Seoul, Korea (Republic of)

**Aims and Methods:** The aim of this study was to determine the optimal timing to add simethicone for improving bowel preparation during colonoscopy using PEG-Asc. Antifoaming agent, simethicone was known to enhance colonic visualization during colonoscopy.

**Conclusions:** Bowel preparation with PEG-Asc plus simethicone eliminates air from the colon more effectively. Furthermore, adding simethicone at the optimal time could improve the quality of bowel preparation, especially enhancing diminutive PDR.

**Disclosure:** Nothing to disclose.

**P0460 PUBLIC ATTITUDES TO COLONOSCOPY: HOW MUCH BOWEL PREPARATION LIQUID MUST BE DRUNK BEFORE A COLONOSCOPY?

B Amlani1, F Radaelli2, P Bhandari3

1 Norgine Ltd., Medical Affairs, Harrow, United Kingdom 2 Faludze Hospital, Chief, Endoscopy Unit, Department of Gastroenterology, Como, Italy 3 Portsmouth University Hospital, Dept. of Gastroenterology, Portsmouth, United Kingdom

**Introduction:** In European countries, public beliefs and attitudes to bowel preparation before colonoscopy are poorly understood. A survey was conducted to address the issue.

**Aims and Methods:** An online survey was conducted in 5 large European countries (UK, Germany, France, Spain, and Italy), among members of the general public who had not had a colonoscopy. A total of 10 questions asked: Before a colonoscopy can be undertaken, the colon must be cleaned by the patient drinking a bowel preparation solution. How much of the bowel preparation liquid do you think a patient needs to drink prior to the procedure? The survey targeted 500 people aged 18–70 years from each country, and aimed to balance respondent groups for region, gender, age, and occupation.

**Results:** Among 53,795 invited persons, 18,650 (35%) responded to the survey and 2,500 (5%) completed the survey who had never had a colonoscopy before across the 5 assessed EU countries. Among these, 13% respondents believed they had to drink maximally 1½-litre bowel preparation liquid. 16% believed they must drink between 1½ and 1 litre, while 38% thought they must drink 1 whole litre. Fewer, 22%, expected to drink 2 litres, and only 12% believed they must drink more than 2 litres. Taken together, nearly 9 out of 10 potential colonoscopy patients expected to drink maximally 2 litres of bowel preparation liquid to accomplish their colon cleansing. The national levels were comparable except for Germany, where only 8 out of 10 respondents expected to drink maximally 2 litres.

**Conclusion:** The vast majority of people in UK, Germany, France, Spain, and Italy expect to drink 2 litres or less of a bowel preparation liquid before a colonoscopy. Such widespread public beliefs could potentially collide with clinical practice where patients must often drink 3 litres or more to adequately prepare their bowel. The new availability in Europe of highly effective low-volume bowel preparations such as the 1 L polyethylene glycol NER1006 can help close this perceptual gap whilst ensuring reliable cleansing success at a reduced fluid volume intake.

**Disclosure:** Amlani B, employee of Norgine; Radaelli F, speaker and advisory board member for Norgine, Boehringer Ingelheim; Bhandari P, nothing to disclose.

**P0461 GENOMIC MEDICINE IN GASTROENTEROLOGY, PRESENT AND FUTURE: A NATIONWIDE SURVEY OF UK GASTROENTEROLOGY TRAINEES

I Al Bakiri1,2, G.M. Selupos-Rogers2, H. Burton2, K.J. Monahan3

1 Barts Cancer Institute, Centre for Tumour Biology, London, United Kingdom 2 St. Mark’s Hospital, Gastroenterology Department, Harrow, United Kingdom 3 Barts Health NHS Trust, Gastroenterology Department, London, United Kingdom

**Introduction:** Genomics and personalised medicine are increasingly relevant for patients with gastrointestinal conditions. In the United Kingdom, the higher training curricula of other specialities (e.g. cardiology and oncology) have been revised with the addition of modular training in genomics. We aim to capture the current state of genomics training in gastroenterology in the UK to review current understanding, clinical experience and long-term training needs of trainees, and to assess their preparedness for future consultant practice.

**Aims and Methods:** A web-based nationwide survey of all UK Gastroenterology specialty trainees was carried out in November and December 2017, supported by the British Society of Gastroenterology national training committee.

**Results:** 100 trainees (representing 15.2% of the 658 UK gastroenterology trainees) across 17 of 18 regions responded to this survey, representing a full range of gastroenterology registrar training levels. Only 9% and 16% of trainees believe that their local training programme adequately prepares them for future clinical practice utilising genomic medicine and personalised medicine respectively. Barriers identified (with percentage agreeing or strongly agreeing in parentheses) include the need for greater education of trainees (93%), inadequate clinical guidance to base interventions on the results of genomic testing (53%), concerns over misinterpretation by patients (43%) and overuse/misuse of testing by clinicians (34%).

When assessing current mainstream genetic and personalised tests, trainees felt prepared to perform HFE genotyping (98%), assess TPMT status (97%), and...
interpret HLA typing for suspected coeliac disease (85%). However, only a minority of these felt prepared to perform the following investigations: poly-
posis screening (34%), hereditary pancreatic cancer screening (30%), testing for Lynch Syndrome (33%), and KRAS testing for colorectal cancer (20%). For their future
clinical practice, 76% of trainees did not know what mainstreaming of genomics would entail, with only 6% of trainees having recruited patients for the UK
100,000 genomics project.

Most trainees would support having dedicated training days on genomic medi-
cine (83%), formal training provisions for the mainstreaming of genomic testing (64%), an update to both the UK gastroenterology specialist training cur-
as well as the specialty examinations (57%), and better-defined pathways for referral to local genomic services (91%).

Conclusion: Most British gastroenterology trainees feel ill-equipped to practise genomics and personalised medicine as consultants, at a time of progressive main-
streaming of genomic practice in our specialty. We propose that the UK gastro-
enterology specialty curriculum requires specific revision to prepare trainees for
genomics in their future clinical practice, and recommend that other European gastroenterology training programmes also assess their local genomic training
requirements.

Introduction: Up to 25% of fecal occult blood test (FOBT)-positive participants of colorectal cancer (CRC) screening programs fail to show up for colonoscopy. For
to many of them, the main obstacle is not lack of information, oppositional
personality or denial, but rather a fear of finding out that they have cancer. The
fear paralyzes their ability to start the work up. At the same time, they are
completely aware of and frightened of the potential consequences of not under-
going the test. This unresolved emotional stress leads to feelings of anxiety and
grip, and often results in coping by self-explanations as to why the need for the
test may not apply in their case, doing repeated FOBTs in the hope the results
will be normal, and procrastination - the practice of performing less urgent tasks
in preference to more urgent ones, to transfer attention away from it. Physicians
often mistake coping mechanisms as patient resistance. Motivational interview (MI)
is a psychological intervention technique designed to facilitate a patient’s awareness of the barriers, and aimed to challenge the
feeling of colorectal cancer (CRC) screening programs fail to show up for colonoscopy. MI is an efficient and
valuable tool, and in our cohort helped 38% of patients to overcome this barrier.

Introduction: As of 2009, 19 out of 27 EU countries had a program for colorectal cancer (CRC) screening, with at least 3 countries currently using flexible sigmoidoscopy (FS). FS is the only cancer screening test proven to reduce all-cause mortality in randomized controlled trials. We hypothesize that this unique all-
cause mortality reduction is attributable to colorectal cancer prevention rather
than early detection.

Aims and Methods: Exploration of the relationship between mortality reduction and CRC prevention in randomized controlled trials of CRC screening. Study
Design: Random effects meta-analysis with correlation of study outcomes using
Pearson correlation coefficient followed by linear regression for statistically

significant correlations. Setting or Dataset: Randomized controlled trials specified in the U.S. Preventive Services Task Force 2016 Evidence Report for Colorectal Cancer Screening. Patients: 786,769 normal risk males and females age 45 to 80 years. Interventions: CRC screening with FS or fecal occult blood test (FOBT). Main and Secondary Outcome Measures: All-cause mortality, CRC incidence, mortality attributed to CRC, quantitative comparison of these outcomes for different tests, and correlations of these outcomes.

Results: FS reduces all-cause mortality (relative risk [RR], 0.975; 95% CI, 0.958–0.992) and reduces CRC incidence (RR, 0.79; 95% CI, 0.74–0.84) at 10.5–11.9 years of follow-up, with an all-cause mortality reduction which shows a strong linear correlation with CRC incidence reduction (R, 0.95; 95% CI 0.42–0.99). FOBT does not reduce all-cause mortality (RR, 1.001; 95% CI, 0.992–1.010) nor CRC incidence (RR, 0.96; 95% CI, 0.89–1.02) but does reduce mortality attributed to CRC (RR, 0.78–0.91) at 15.6–30.0 years. Conclusion: All-cause mortality reduction displays a dose-response relationship with CRC prevention and regression analysis indicates that CRC prevention is the sole mechanism of action affecting all-cause mortality in these trials. Early detection of CRC does not appear to reduce all-cause mortality. These findings should inform updated recommendations for effective CRC screening in populations.

P0467 ABERRANT EXPRESSION OF SPP1 THROUGH DOWNREGULATION OF HELIOS IN GASTRIC CANCER

W.-M. Chen1, C.-S. Wu1, K.-L. Wei1, Y.-F. Deng1, Y.-L. Chang2, W.-T. Hsu3, S.-F. Wu2, C. Li2

Introduction: Helios remains a cancer-testable biomarker. The activation of Helios in gastric cancer is driven by the dysregulation of cytokine signaling. In this study, we aimed to elucidate the expression of Helios in gastric cancer cell lines and its regulatory mechanism between Helios signaling and miR-590-5p.

Aims and Methods: To elucidate the Helios function in gastric cancer cells, we used 1K2F2-targeting CRISPR-Cas9 system to knock-out Helios expression in AGS cell line. The CCK8-dependent proliferation assay, wound healing assay and invasion assay were performed. We further analyzed the gene expression between AGS and AGS-KO cells by next generation sequencing (NGS), and finally validated the gene expression in AGS and AGS-KO cells by qRT-PCR.

Results: K RK34 expression was significantly decreased, while the mobility and invasiveness were increased in Helios knockdown AGS cells compared to parental cells. The data of NGS indicated an increase of SPP1 expression upon depletion of Helios, and increased in Helios knockdown AGS cells compared to parental cells. The data of qRT-PCR further confirmed to be a direct target of miR-590-5p. Their expressions showed a negative correlation in primary GC samples (r = -0.278, p < 0.001, n = 367), miR-590-5p suppressed the tumorigenic properties of GC cells. Re-overexpression of Helios partly reversed the tumor-suppressive effect of miR-590-5p.

Conclusion: Helios is overexpressed and plays a tumorogenous role in gastric cancerogenesis. The activation of Helios in gastric cancer is partly due to the silence of a tumor-suppressive miRNA, miR-590-5p. These findings comprehensively deciphered the regulatory mechanism between Helios signaling and miR-590-5p, which might imply a constructive therapeutic intervention in GC.

Disclosure: Nothing to disclose

P0408 METHYLOMICS ANALYSIS IDENTIFIES SPG20 AS A SENSITIVE NON-INVASIVE BIOMARKER FOR EARLY DETECTION OF GASTRIC CANCER

K.-L. Wei1, C.-S. Wu1, Y.-C. Chen1, M.W.Y Chan2
1Chang Gung Memorial Hospital, Chia-Yi, Taiwan, Division of Gastroenterology, Chia-Yi, Taiwan
2National Chung Cheng University, Biomedical Sciences, Chia-Yi, Taiwan

Contact E-Mail Address: kittychen1020@gmail.com

Introduction: Gastric cancer remains a cancer with high incidence and poor long-term survival in Taiwan, despite of the effort to eradicate H. pylori infection. Helios belongs to Ikaros family proteins, which perform as tumor suppressors because many studies reported that abnormal expressions of these proteins. Helios belongs to Ikaros family proteins, which perform as tumor suppressors. However, the clinical significance of aberrant epigenetic silencing of STAT3 targets in gastric cancer is not fully understood.

Aims and Methods: To identify STAT3 targets that are epigenetically silenced by STAT3 in gastric cancer, Illumina 850K methylation microarray was performed in AGS gastric cancer cells and cells depleted with STAT3. Bisulphite pyrosequencing or methylation-specific PCR (MSP) was also performed to examine promoter methylation of the identified targets in tissue or serum/plasma samples from patients with gastric cancer (n = 53), IM (n = 8), gastritis (n = 12) and a panel of gastric epithelial cells including cancer cell lines. We further explored a methylomic drug treatment by DNMT inhibitor together with qRT-PCR to use DNA methylation in the expression of the identified targets.

Results: Integrative methylation microarray and computational analysis identified STAT3 targets that showed epigenetic silencing in STAT3 depleted AGS cells. To confirm our results, bisulphite pyrosequencing confirmed that promoter region of SPG20 was hypermethylated in a panel of gastric cancer cell lines including AGS cells but not in GE2 immortalized gastric epithelia. These results were expected, SPG20 is highly downregulated in a panel of gastric cancer cell lines in which the expression can be restored by the treatment of DNMT inhibitor thus suggesting that SPG20 is epigenetically silenced by promoter methylation. To determine the clinical significance of SPG20 methylation in gastric cancer, we examined promoter methylation of SPG20 in 53 paired of gastric cancer patient samples, 8 samples of intestinal metaplasia (IM) and 12 samples of gastritis by bisulphite pyrosequencing. Interestingly, promoter methylation of SPG20 is significantly higher in cancer tissues than that of gastritis (p < 0.01 and p < 0.05). In addition, there is no association between SPG20 methylation and tumor grade, stage and patient’s survival suggesting that methylation of SPG20 may be an early event. To confirm this hypothesis, we performed methylation specific PCR (MSP) in cDNA isolated from serum samples of gastric cancer (n = 53), IM (n = 5) and gastritis (n = 9). Interestingly, SPG20 methylation showed a progressive increase in tumor progression (SPG20 methylation% in gastritis = 37.5%, IM = 66.7%, cancer = 91.7%, p < 0.05).

Conclusion: Taken together, SPG20, a potential STAT3 target, is frequently hypermethylated in gastric cancer. Methylation of SPG20 may be a novel non-invasive biomarker for early detection of gastric cancer.

Contact E-Mail Address: c.vaidas@yahoo.com

Introduction: Hyperthermic intraperattional chemotherapy (HIPEC) is a treatment method to cure intraperattionally spread gastric and ovarian cancer. Although a number of clinical trials report satisfactory results, data remains controversial. Heat shock proteins are known being responsible for cellular resistance to temperature. HO-1 is a heat shock protein, which is induced by hyperthermia.

Aims and Methods: To identify the therapeutic strategy for ovarian cancer, we performed in vitro cell survival assay with combination of HO-1 silencing by siRNA and hyperthermia. The results showed that HO-1 silencing in ovarian cancer cells (A2780, A2780/DOX) improved the response to hyperthermia. These results suggest that HO-1 silencing might enhance the therapeutic effect of HIPEC in ovarian cancer.

Conclusion: HO-1 silencing may enhance the therapeutic effect of HIPEC in ovarian cancer.

Disclosure: Nothing to disclose
Aims and Methods: The aim of our in vitro study was to clarify the response of gastric and ovarian cancer cells to hyperthermia and cisplatin, following the modulation of HO-1 expression. AGS (gastric adenocarcinoma), OVCAR-3 (ovarian adenocarcinoma) cells were treated with different temperature regimes (normothermia: 37°C; and hyperthermia: 43°C) either with cisplatin for one hour. Prior the treatment experimental groups of cells were HO-1 silenced by siRNA transfection. MTT was used to evaluate cells viability. Apoptosis was assessed by flow cytometry, using Annexin V-PE and 7AAD. Real-time cell analysis was used to evaluate the changes of viable cell rates in real time manner. HO-1 expression was detected by QRT PCR and Western blot.

Results: Cisplatin increased HO-1 expression by 3.73-fold in normothermia and 2.4-fold in hyperthermia for OVCAR-3 cells. Hyperthermia stimulated the increase of HO-1 expression significantly by 1.34-fold. HO-1 expression was not affected neither by temperature, nor by cisplatin in AGS cells. In OVCAR-3 protein level, HO-1 expression was increased similarly as for RNA - by cisplatin not affected neither by temperature, nor by cisplatin in AGS cells. In OVCAR-3 an analyzer was used to evaluate the changes of viable cell rates in real time.

Conclusion: Cisplatin and hyperthermia enhanced this effect by additional 20%. In AGS cells, HO-1 silencing reduced viability at 43°C resulted in drop of cells viability by 36% and HO-1 silencing enhanced this effect by additional 20%. In AGS cells, HO-1 silencing reduced the viability by 16% at 37°C. HO-1 silencing in normothermia increased apoptosis rates by 3.09-fold and 6.84-fold in OVCAR-3 and AGS cells respectively. Real time cell analysis showed that exposure to cisplatin gradually decreased cell index of OVCAR-3 and AGS (HO-1 silenced) cells in normothermia. Hyperthermia enhanced this effect in OVCAR-3 cells, while AGS cell index stayed similar.

Disclosure: Nothing to disclose.
P0474 EFFECT OF MYD88 DEFICIENCY ON INTESTINAL INFLAMMATION AND MICROBIOTA IN COLITIS MICE

F Xiao1, Z Ye1, J Li2, J Han1, J Liao1, Q Zhou1, M Liu1, U Seidler1, D A Tian2

Contact E-Mail Address: christinafxi@126.com

Introduction: MyD88 is a key signaling adaptor for TLRs and involved in intestinal microbiota-host interaction associated innate and adaptive immune. This study aims at investigating the effect of MyD88 on colonic inflammation and gut flora.

Methods and Aims: MyD88 knockout mice and their wild-type littermates were kept under the same environment except for treated with normal drinking water (WT) or 3% DSS (WT-DSS) or 3% DSS and WT-DSS (WT-DSS groups) for 7 days. Disease activity index (DAI) and histological score of colitis (HS) inflammatory cytokines were evaluated to determine the colonic inflammation severity. TGF-β1, EGF, COX-2 and tight-junction (T-J) protein mRNA was measured by qPCR to access epithelial restoration. NF-κB activation was evaluated by Western-blotting and measured by Grey-scale value. Proximal colonic mucosa was used to analyze gut mucosal flora using high-througput sequencing analysis targeting V4-V5 regions of the bacterial 16S rRNA gene. Statistical analysis was performed using one-way ANOVA analysis and the Post hoc LSD test or Tamhane's T2 test.

Results: Colonic NF-κB activation was significantly inhibited in MyD88-DSS group compared to WT-DSS group, suggesting the inhibitory effect of MyD88 deletion on NF-κB activation. However, deletion of MyD88 failed to improve DAI and HS in DSS-colitis mice as compared to WT-DSS group. Besides, the difference of colonic IL-1β, TNF α and IFN γ mRNA expression drastically decreased in MyD88 deficient mice with or without DSS challenge. TGF-β1, EGF, COX-2 and T-J protein mRNA was not significantly different among groups, suggesting relatively normal epithelial reconstruction ability in WT-DSS, MyD88 KO and MyD88-DSS groups as compared to WT group.

Colon mucosal morphology analysis showed that the alpha diversity was not significantly different among groups in terms of diversity index (Shannon and inverse Simpson) and bacterial culture abundance (Chao). At phylum level, the proportion of Proteobacteria dramatically elevated to 41.9% in MyD88 KO mice as compared to WT, WT-DSS and MyD88-DSS groups (7.0%, 16.1% and 22.3%, respectively), within which pathogenic bacteria such as Pseudomonadiales, Burkholderiales and Enterobacteriales were predominately increased at order level in MyD88 KO mice. The percentage of probiotics such as Lactobacillus decreased in MyD88 KO group (31.5%) and further dropped to 11.2% and 4.1% in WT-DSS or MyD88-DSS groups as compared to WT (35.5%).

Conclusion: Deficiency of MyD88 inhibited NF-κB activation but not colonic inflammation in mice with colitis possibly due to MyD88 deletion associated pathogenic-riched and probiotics-exhausted gut microbiota.

Disclosure: Nothing to disclose

P0475 PILOT STUDY ON THE EFFECTIVENESS OF THE COMBINATION OF HYALURONIC ACID, COINDRITIN SULFATE AND POLYOXAMER 407 IN SCAR HEALING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION OF THE ESOPHAGUS IN PORCINE DISEASE

A Amoros Tenorio1, M J Caballero Cansino2, Y Brito Casillas2, E Rodriguez Grau-Bassas2, M San Juan Acosta1
1University Hospital Nuestra Señora de Candelaria, Endoscopy Unit, Santa Cruz de Tenerife, Spain
2University of Las Palmas Gran Canaria, General Experimental Animal Research Service, Las Palmas Gran Canaria, Spain

Introduction: Hyaluronic acid + chondroitin sulfate + poloxamer 407 (HA+CS) has shown efficacy in the repair of microscopically-damaged esophageal epithelium caused by gastrointestinal reflux (GER). However, there are no studies that show efficacy in the repair of macroscopic damage of the mucosa and/or submucosa.

Aims and Methods: Primary Objective: To assess the efficacy of HA+CS in healing scar due to deep submucosal injury after endoscopic submucosal dissection (ESD) of the esophagus in porcine models. Secondary Objective: To evaluate the efficacy of HA+CS in the prevention of esophageal stenosis secondary to ESD. This was a randomized, experimental, endoscopists- and pathologist-blinded pilot study. Dissection of 4% of the middle-dorsal esophagus was performed in 6 anesthetized pigs (female Landrace-Large Whites). In 3 pigs (C1, C4 and C5) 10 ml of HA+CS (1 sachet) was injected on the surface of the eschar, infiltrating it with a syringe on the submucosa of the eschar edges. This was followed by treatment with HA+CS sachet every 2 days + Omeprazole 20 mg/d (CS). The other 3 pigs received only the standard treatment, Omeprazole 20 mg/12h po, to avoid potential additional damage from GER. The pigs were kept on a liquid diet for the first 24 hours and then started on a regular diet. After 15 days, an endoscopic evaluation was conducted to assess the degree of stenosis and healing grade using the modified Manchester scale for the clinical evaluation of scars. Finally, histological analysis was conducted by 2 pathologists, following necropsy.

Results: The average weight at the beginning of the study for the HA+CS group was 44.63 kg and 44.13 kg respectively, and 36.48 kg vs 41.80 kg respectively at the end of the treatment. There were no differences in the mean size of eschars (9.9 mm in the HA+CS group vs 8.82 mm in control group) or in their location (15.66 mm from the gastrooesophageal junction in the HA+CS group vs 11.66 mm in the control group). All the eschars covered more than 50% of the circumference. Stenosis presented in 100% of the cases. In 2 (33.3%) cases, the endoscope could be passed through the stricture (C2 and C6). The score on the modified Manchester scale was 4.3 for the HA+CS group and 3.3 for the control group.

Complications: perforation with paraesophageal collection in C4. Histological analysis: Higher inflammatory infiltrate with predominance of neutrophils, lymphocytes, macrophages (acute inflammatory reaction) in the control pigs vs. the pigs treated with HA+CS, and there was no inflammatory infiltrate (lymphocytes) predominated. In the control group, neovascularization consisted of small to medium vessels and the reorganization of the connective tissue process was in its beginning phase, whereas in the HA+CS group the blood vessels were increased and the reorganization of the connective tissue was more advanced, as evidenced by the presence of fibroblasts well organized in parallel lines. 1 of the HA+CS-treated pigs showed re-epithelialization on 1 border (C1).

Conclusion: The histological results suggest that HA+CS promotes the repair of esophageal mucosa after ESD, although a clinically significant difference to control treatment was not shown, as all the pigs developed stenosis. More studies are required, with a larger sample size, to evaluate the efficacy of HA+CS in the repair of macroscopic damage of the mucosa.

P0476 PANCOLITIS INCREASES THE MORTALITY RISK OF CYTOMEGALOVIRUS COLITIS IN PATIENTS WITHOUT INFLAMMATORY BOWEL DISEASE: A RETROSPECTIVE COHORT STUDY

P-H Le1, C-T Chiu2
1Linkou Chang Chung Memorial Hospital, Department of Gastroenterology and Hepatology, Taoyuan City, Taiwan
2Taiwan Association of the Study of Small Intestinal Disease, Taoyuan City, Taiwan
Contact E-Mail Address: puohsien@gmail.com

Introduction: Cytomegalovirus (CMV) colitis typically presents in immunocompromised patients, such as IBD patients. Several studies have been conducted on the endoscopic findings of CMV colitis in IBD patients; however, those of CMV colitis in non-IBD patients and their relationship with in-hospital mortality are unclear.

Aims and Methods: We aimed to describe the endoscopic presentation in these patients and to determine the endoscopic predictor of in-hospital mortality. Patients with CMV colitis diagnosed using histology between April 2002 and December 2016 at the Linkou Chang Chung Memorial Hospital, Taiwan, were retrospectively enrolled. Patients diagnosed with IBD during follow-up were excluded. Patient data, including underlying diseases, endoscopic presentation, laboratory data, clinical course, complications and clinical outcomes were collected. The independent risk factors for in-hospital mortality were analysed with logistic regression. The difference of overall survival was compared with Kaplan-Meier survival curve and log rank test. All statistical calculations were performed using SPSS software, version 21 (IBM, Armonk, New York).

Results: 69 patients were enrolled, including 8 IBD patients. Within the 61 non-IBD patients, 31 were diagnosed by colonoscopy and others by sigmoidoscopy. Ulceration (77%) was the most common endoscopic finding, followed by a cobble stone appearance (19.7%), colitis with without erosions (9.8%), pseudomembrane (9.8%) and tumour/polyp-like lesions (8.2%). Among the patients who underwent full-length colonoscopy, 35.3% presented with right-sided colitis, 23.5% with left-sided colitis and 32.4% with pancolitis. Pancolitis was identified as a negative predictor of in-hospital mortality (odds ratio, 6.8; 95% confidence interval, 1.233-37.497; p = 0.028) and overall survival (log rank p = 0.018).

Conclusion: Colonoscopy is recommended for precise CMV colitis diagnosis and outcome prediction in non-IBD patients.

Disclosure: Nothing to disclose

P0477 CLOSTRIDIUM DIFFICILE ISOLATION AND CHARACTERISATION - RESULTS OF A PILOT STUDY

Pintar1, M Rupnik1, P Šok2
1University Maribor, Maribor, Slovenia
2University Clinical Centre Maribor, Maribor, Slovenia
Contact E-Mail Address: pavel.sok@ukm.si

Introduction: Clostridium difficile (CD) infection can lead to severe infectious colitis. Different bacterial toxins and diminished host immune response contribute to symptomatic disease. Inflammatory bowel diseases (IBD), ulcerative colitis, and Crohn’s disease are chronic diseases causing a prolonged inflammation of gastrointestinal tract. In these patients colonisation with CD is often confirmed but its role is inconclusive.

Aims and Methods: The aim of the study was to compare CD colonization and selected inflammatory parameters in patients with IBD and other diseases in
hospitalized patients. We obtained fecal samples from 161 randomly selected patients, hospitalized at Department of Gastroenterology during the period between 1/1/2015 - 1/5/2016. Total DNA was isolated from feces and CD was detected using the real time PCR amplification of specific 16S RNA gene and toxicogenic strains were confirmed by the amplification of tcdB gene. After collecting information, inflammatory parameters (neutrophil granulocytes, leukocytes, CRP, erythrocyte sedimentation, albumin, ferritin, and iron) and therapy (pre-and hospital antibiotics, corticosteroids, biological therapy) we divided isolates in 2 groups: IBD group and control group.

Results: The final analysis included 151 samples, (male 75, female 76), 48 (31.8%) were positive for CD, 11 of which (11/103, 10.7%) were tcdB+. Between the 2 groups, significant differences were confirmed only in the use of corticosteroids and biological therapy prior to hospitalization, p < 0.01. Regarding the use of antibiotics prior to hospitalization, differences between the 2 groups were not confirmed, p = 0.72. There were no significant differences observed in inflammatory parameters within IBD patients (CD positive compared to CD negative).

Conclusion: The results of our study suggest that IBD patients and patients from the control group were colonized with CD in comparable proportions. The majority of strains were nontoxicogenic, which will not cause CD infections, but could be regarded as a marker for disturbed gut microbiota.

P0478 UNIVERSAL ANTIBIOTIC PROPHYLAXIS MAY BE UNNECESSARY IN ACUTE VARICEAL BLEEDING: A SINGLE-CENTER RETROSPECTIVE STUDY

M Ueno, T Kayahara, H Takabatake, Y Morimoto, M Mizuno
Kurashiki Central Hospital, Department of Gastroenterology and Hepatology, Kurashiki, Japan

Contact E-Mail Address: mu3951@kchnet.or.jp

Introduction: Randomized controlled trials conducted from the 1990s to early 2000s showed efficacy of antibiotic prophylaxis in acute variceal bleeding. Over the past decades, however, endoscopic and systemic therapy for variceal bleeding has improved remarkably, and the necessity of antibiotic prophylaxis could have decreased.

Aims and Methods: In this study, we aimed to evaluate the efficacy of antibiotic prophylaxis with our most recent data. We retrospectively studied clinical characteristics, treatment and outcomes of 150 patients (116 men, median age: 62 years) with acute variceal bleeding, who were admitted to our hospital between January 2012 and December 2016. Those who had obvious infection or aspiration pneumonia at admission were excluded. Patients were classified into 2 groups according to presence or absence of antibiotic prophylaxis. Rates of obvious bacterial infection, suspicious infection, in-hospital mortality, in-hospital rebleeding, and readmission within 30 days were compared between the 2 groups.

Multivariate analysis was also performed to evaluate the efficacy of antibiotic prophylaxis.

Results: The median Child-Pugh score was 8. Immediate endoscopy was performed in 148 patients, and active bleeding was observed in 80 patients. Endoscopic variceal ligation was performed in 111 patients. Hemostasis was achieved in 148 patients. 2 patients died of uncontrollable bleeding (1 with and 1 without endoscopy). 46 patients (30.7%) received antibiotic prophylaxis. The rates of obvious bacterial infection, suspicious infection, in-hospital mortality, in-hospital rebleeding, and readmission within 30 days were not different significantly between the 2 groups. In the multivariate analyses, antibiotic prophylaxis was not associated with any of these outcomes. Instead, high serum creatinine levels at admission (greater than 1 mg/dL) were significantly associated with bacterial infection (adjusted odds ratio 12.5, 95% CI 1.24–126), and higher Child-Pugh score (per point) was associated with mortality (adjusted odds ratio 3.57, 95% CI 1.25–10.2).

Conclusion: Universal antibiotic prophylaxis may be unnecessary in acute variceal bleeding. Impaired renal function at admission was a risk factor for bacterial infection and might be applied to a risk stratification approach for antibiotic prophylaxis.

P0479 AIMS65 IS THE MOST ACCURATE RISK-SCORING SYSTEM FOR PREDICTING MORTALITY OF PATIENTS WITH DUODENAL ULCER BLEEDING

R Hirai, Y Shimodate, S Ishikawa, T Kanatani, M Minami, A Doi, N Nishimura, H Mouri, K Matsueda, H Yamamoto, M Mizuno
Kurashiki Central Hospital, Gastroenterology and Hepatology, Kurashiki, Japan

Contact E-Mail Address: me20070@s.okayama-u.ac.jp

Introduction: In spite of the advance of endoscopic hemostasis for upper gastrointestinal bleeding, treating duodenal ulcer bleeding is sometimes difficult and does not yield good prognosis.

Aims and Methods: In this study, we evaluated and compared various risk-scoring systems for upper gastrointestinal bleeding to predict outcomes of patients who underwent endoscopic treatment for duodenal ulcer bleeding. Bleeding from peptic ulcer was diagnosed in 1,147 patients (892 patients with gastric and 255 with duodenal ulcer) among 7,106 patients who underwent emergent esophagogastroduodenoscopy for upper gastrointestinal bleeding at our hospital from July 2007 to June 2017. We retrospectively reviewed electronic medical records of the 1,147 patients and compared their prognosis after endoscopic therapy between gastric and duodenal ulcer patients. In the 255 patients with duodenal ulcer, we evaluated the following risk-scoring system: Glasgow Blatchford, AIMS65, admission Rockall and full Rockall scores, to predict inhospital mortality by analyzing their area under the receiver operating characteristic curve (AUROC).

Results: The mortality rate of patients with duodenal ulcer bleeding was 6.7% (17/255), which were significantly higher than that of those with gastric ulcer bleeding (0.67%, 6/892) (p < 0.001). In the duodenal ulcer patients, risk scores were significantly higher in patients with in-hospital mortality than those without in the following systems, and AUROC of AIMS65 (0.83) was highest among them (Table). With more than 2 points of AIMS65 score as a cut-off value, sensitivity and specificity to predict in-hospital mortality of patients with duodenal ulcer bleeding were 0.882 and 0.597, respectively.

Conclusion: The conclusion of patients with duodenal ulcer bleeding was poorer than that of patients with gastric ulcer. The AIMS65 score may be useful to predict the outcome after endoscopic treatment for duodenal ulcer bleeding, especially in the situation at deciding the indication of endoscopic hemostasis because this scoring system can be calculated without endoscopic findings.

Disclosure: Nothing to disclose

P0480 EFFECTS OF ASPIRIN ON MORTALITY AND RE-BLEEDING IN PATIENTS WITH NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING: A SYSTEMATIC REVIEW AND META-ANALYSIS

R Aoun1, J Hashash1, N El-Majoub2, A Khannis1, D Rockey2, E Akli2, K Barada1
1American University of Beirut Medical Center, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Beirut, Lebanon
2Medical University of South Carolina, Internal Medicine, Division of Digestive and Liver Diseases, Charleston, United States

Contact E-Mail Address: ra242@aub.edu.lb

Aims and Methods: Our primary aim was to synthesize the evidence comparing mortality and re-bleeding rates in patients who resume aspirin compared to those who do not after NVUGIB. Our secondary aim was to determine whether being on aspirin upon presentation with NVUGIB is associated with worse outcomes compared to not being on it.

We conducted a systematic review of randomized controlled trials (RCTs) and observational studies. We ran a comprehensive sensitive search covering major electronic databases, clinical trial registries and grey literature. 2 teams of 2 reviewers screened titles and abstracts of included studies and assessed their risk of bias using standardized forms. We used meta-analysis to pool data for mortality and re-bleeding outcomes.

Results: Of 9827 citations, we assessed 254 full-texts for eligibility. 1 RCT and 3 observational studies address the primary question; all assess low dose aspirin, but timing of its resumption varied. None compare different times of aspirin resumption. The RCT suggests that early aspirin resumption may reduce mortality; HR = 0.29; 95% CI [0.06–0.65]; moderate certainty of evidence.
Meta-analysis of 3 observational studies suggests that aspirin resumption may reduce the risk of rebleeding: pooled HR = 0.79; 95% CI [0.60-1.02]; very low certainty of evidence. We assessed if the relative effect of resuming aspirin is modified by whether people were using it for secondary or primary prophylaxis. In those on aspirin for secondary prophylaxis, resuming aspirin may reduce mortality to a large extent (HR = 0.56; 95% CI [0.31–1.00]) compared to those taking it for primary prophylaxis (HR = 4.07; 95% CI [0.54–30.74]), but studies were characterized by high heterogeneity (p = 0.06 for subgroup effect). The RCT suggests that aspirin resumption may increase re-bleeding: HR = 1.90; 95% CI [0.60–6.00]; moderate certainty of evidence, while meta-analysis of 2 observational studies suggests it may reduce re-bleeding: pooled HR = 0.82; 95% CI [0.35–1.91]; very low certainty of evidence. Meta-analysis of 2 studies shows no increased re-bleeding risk: pooled HR = 1.23; 95% CI [0.44–3.42]; very low certainty of evidence.

Concluding a protective strategy soon after NVUGIB is of very low certainty based on observational studies and moderate certainty based on 1 RCT. The available evidence is not informative as to the optimal timing of aspirin resumption. High quality RCTs are needed to address the optimal timing of aspirin resumption in patients with NVUGIB.

Disclosure: Nothing to disclose.

### P0481 OPTIMAL ENDOSCOPY TIMING ACCORDING TO THE SEVERITY OF UNDERLYING LIVER DISEASE IN PATIENTS WITH ACUTE VARICEAL BLEEDING

C.W Huhä, D.H Jungb, J.S Kimc

1Incheon St. Mary’s Hospital, The Catholic University of Korea, Department of Internal Medicine, Incheon, Korea (Republic of)
2Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea (Republic of)
3Incheon St. Mary’s Hospital, The Catholic University Of Korea, Incheon, Korea (Republic of)

Contact E-Mail Address: hlcwh@catholic.ac.kr

Introduction: Current guidelines recommend endoscopic therapy to be performed within 12 hours for acute variceal bleeding (AVB). However, the optimal timing of endoscopic therapy for AVB remains unclear.

Aims and Methods: The aim of this study was to examine the relationship between the endoscopy timing and clinical outcomes in AVB, with emphasis on Forrest classification and endoscopic therapy. From January 2010 to June 2015 in 3 center, 1287 patients with varices confirmed as the source of bleeding by endoscopy were evaluated. The primary outcome was a composite of 6-week rebleeding and mortality. We stratified patients according to the model for end-stage liver disease (MELD) score and analyzed the association between the endoscopy timing and primary composite outcome.

Results: In 411 patients, the overall composite outcome rate was 30.9% (n = 127) at 6 weeks. Patients who underwent urgent endoscopy (<12 hours) had a significantly higher composite outcome than patients who underwent endoscopy (>12 hours) (34.4% vs. 19.1%; p = 0.005). Low-risk patients who underwent urgent endoscopy were more likely to reach the composite outcome (adjusted OR, 0.84 per 4 hours; 95% CI, 0.67-0.98; p = 0.027). However, time to endoscopy did not have a significant impact on outcomes in high-risk patients. These findings persisted even after adjustment for baseline characteristics between the urgent and non-urgent groups.

Conclusions: Our results are significant and are associated with a poorer outcome in patients with AVB, especially in low-risk patients. This result provides a treatment strategy according to the severity of underlying liver disease in patients with AVB.

Disclosure: Nothing to disclose.

### P0482 FORREST CLASSIFICATION DOES NOT PROPERLY ASSESS REBLEEDING RISK OR MORTALITY IN HIGH-RISK UPPER GI BLEEDING

E Redondo-Cerezoa, R Jimenez-Roualasa, F Vadillo-Callesa, F Valverdea, M Lopez de Hierroc, J Martinez-Carak

University Hospital ‘Virgen de las Nieves’, Gastroenterology and Hepatology Unit, Granada, Spain

Contact E-Mail Address: eredondoec@gmail.com

Introduction: Forrest classification has been the most endoscopic used 1 in upper GI bleeding. The 6 stages risk assessment establishes the higher risk in Forrest Ia patients with Forrest IIa and Forrest I, regarding rebleeding risk, because it has been previously suggested that a visible vessel might entail a higher risk of rebleeding. Upper GI bleeding from Virgen de las Nieves University Hospital is a prospectively collected database from January 2013. For this study, patients up to January 2017 were included. For every patient 150 clinical and biochemical variables are recorded. Variables were compared with SPSS 17 software (SPSS Inc. Chicago, IL) by means of the Chi-square test.

Results: 414 patients were included (65.5% males) with non variceal upper GI bleeding. Mean age was 65 years (range 19-97). The main upper GI bleeding etiologies were duodenal ulcer in 29%, gastric ulcer in 22%, acute gastric erosions in 13%, Mallory-Weiss and esophageal ulcers in 8%. 34 patients died (8.2%) and 69% had a relevant comorbidity. An endoscopic therapy with 2 methods (injection plus clipping or argon plasma coagulation) was applied to every patient.

Mortality did not significantly differ between Forrest Ib patients and Forrest IIa (19.6% vs. 20.8%). Regarding rebleeding, despite the proportion of rebleeding patients with Forrest IIa ulcers almost doubled Forrest Ib (20% vs. 10%), the statistic test did not reach statistical significance, neither did regarding the need for surgery (16% vs. 6.5%, p = n.s.). Moreover, when mortality rates in patients with Forrest Ib and Ib were compared we found no significant differences, an trend toward a higher mortality in Forrest IIa patients (15.4% vs. 21.7% IIa). A significant absence of statistical differences was observed for the rest of outcomes studied: rebleeding (23.1% Ia vs. 16.7% IIa) and need for surgery (23.1% Ia vs. 12.5% IIa).

Conclusion: Our study shows that Forrest classification seems an inadequate predicting tool for rebleeding in its actual formulation. In view of our results Forrest IIa patients should probably be considered of a higher risk than Forrest Ib, and closer to Forrest Ia. We might hypothesize that the presence of a visible vessel carries a higher risk of rebleeding, as the presence of more than 4 vessel, close to the vessel, more local coagulation and more coagulation of capillaries, more easily coagulated through endoscopy and even natural mechanisms.

Disclosure: Nothing to disclose.

### P0483 RISK FACTORS OF POOR PROGNOSIS AND IMPAIRMENT OF ACTIVITIES OF DAILY LIVING IN PATIENTS WITH HEMORRHAGIC GASTRODUODENAL ULCERS

Mitsui Memorial Hospital, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: ayayadejinya@yahoo.co.jp

Introduction: Although most of hemorrhagic gastroduodenal ulcers (HGU) can be safely treated with endoscopic procedures, some patients with HGU could have poor prognosis owing to comorbidities and medications for antiocoagulation. In this study, risk factors of poor prognosis including mortality and impairment of activities of daily living (ADL) in patients with HGU were examined. In particular, prognosis of elderly HGU patients (≥75 years old) was evaluated in comparison to that of non-elderly (<75 years old) patients.

Aims and Methods: The medical records of 580 patients with endoscopically confirmed HGU (430 men, 159 women; mean age 66.7 years; range 25–95 years) were retrospectively reviewed. Clinical backgrounds and outcomes were compared between patients ≤75 years old (n=394) and ≥75 years old (n=186).

Results: Of 580 patients, 75% patients were elderly HGU patients. The primary outcome was a composite of 6-week rebleeding and mortality. In elderly patients compared to non-elderly (<75 years old) patients, age ≥75 years old (n=28.0 days), and impairment of ADL were evaluated in 28.0 days after occurrence of hemorrhage and, impairment of ADL. Impairment of ADL was defined as admission to care facilities after hospital discharge or requirement of home modification for rehabilitation at home. Evaluated clinical factors were endoscopic features, non- intervention endoscopic procedures, comorbidities, symptoms, medications, vital signs, and blood test results.

Conclusions: There were significant differences in overall mortality (3.8% vs. 7.6%), hospitalization period (16.2±29.3 days vs. 22.8±28.0 days), and mortality of ADL (1.3% vs. 6.7%) between patients <75 years old and those ≥75 years old. Multivariate analysis revealed that independently significant risk factors for overall mortality were age (≥75 years) (odds ratio [OR] 2.25, 95% confidence interval 1.06–4.74), and renal disease (OR 3.38, 95% CI, 1.42–8.01). Risk factors of mortality within 30 days after hemorrhage were age (≥75 years) (OR 3.40, 95% CI, 1.21–9.56), need for interventional endoscopic procedures (OR 3.91, 95% CI, 1.08–14.1), and renal disease (OR 4.3, 95% CI, 1.40–13.2). Finally, risk factors of impairment of ADL were use of proton pump inhibition or prior to hemorrhage (OR 5.83, 95% CI, 2.1–16.2), heart disease (OR 3.06, 95% CI, 1.11–8.3), and age (≥75 years old) (OR 5.07, 95% CI, 1.73–14.9).

Conclusion: High mortality and impairment of ADL were more likely to be observed in elderly HGU patients compared to non-elderly patients. In particular, comorbidity of renal disease and heart disease was a risk of poor prognosis in those subjects. Prophylactic approaches for HGU and early improvement of ADL after HGU occurrence are particularly important in elderly patients with comorbidities.

Disclosure: Nothing to disclose.

### P0484 PALBI - THE PLATELET-ALBUMIN-BILIRUBIN SCORE - A BETTER PREDICTOR OF OUTCOME OF ACUTE VARICEAL BLEEDING

O Elsharawy1,2, E Abdelsamiea, G Gomaa, N Allama, E Rewish1, I Wakde2

1Saleem Medical Center, Heidelberg University, Gastroenterology and Hepatology, Heidelberg, Germany

Contact E-Mail Address: elsharawy.omar@stadtmission-hd.de

Introduction: The albumin-bilirubin (ALBI) score eliminates the need for subjective variables required in the Child-Turcotte-Pugh (CTP) classification and has been validated as a prognostic indicator for patients with HCC. Incorporating platelet count to reflect portal hypertension in the PALBI score improved

Disclosure: Nothing to disclose.
validity in predicting outcome of patients with HCC undergoing resection and ablative therapies.

Aims and Methods: We aimed to evaluate the PALBI score compared to the CTP class for predicting the outcome of acute variceal bleeding. Data of 1517 patients presenting with acute variceal bleeding were analyzed. The CTP class and PALBI score were calculated to mortality. PALBI score was calculated as: $2.02^{*}\log_{10}\text{platelets} + (0.37^{*}\log_{10}\text{bilirubin}) + (0.04^{*}\text{albumin}) + (3.48^{*}\log_{10}\text{platelets}) + (1.01^{*}\log_{10}\text{bilirubin})$. Areas under the receiver-operator characteristics curve (AUROC) were calculated for survival.

Results: PALBI score was more significant in comparison to ALBI, and PALBI-1 patients survived. 332 Patients died during the admission (0.39%), PALBI grade 1, 43 patients (2.8%) PALBI grade 2, 957 patients (4.5%), 434 (29.2%) CTP B and 1014 (66.8%) CTP C; 6 patients had no score. Mean age was 52 years old; 77.5% were males. There were 69 CTP-A patients (4.5%), 432 (29.2%) CTP-B patients, and 278 (18.4%) CTP-C patients.

Conclusion: PALBI better predicts early mortality of patients with acute variceal bleeding than CTP score.

Disclose: Nothing to disclose

P0485 UPPER GASTROINTESTINAL BLEEDING NOT ASSOCIATED TO PORTAL HYPERTENSION: ASPECTS OF EPIDEMIOLOGY AND MANAGEMENT IN A SOUTHERN SPANISH AREA
J A Díaz Jiménez, J Leal Téllez, A R Calle Gómez, F J Correro Aguilar Hospital Universitario Puerta del Mar, UGC Aparato Digestivo, Cádiz, Spain
Contact E-Mail Address: adiazjime@gmail.com

Introduction: The aim of the research was to evaluate different epidemiological and management aspects of Upper Gastrointestinal Bleeding not associated to Portal Hypertension (UGBNPH) in a Southern Spanish Hospital (Cádiz, Spain).

Aims and Methods: Retrospective research including every patient admitted to Gastroenterology Department of Puerta del Mar Hospital (Cádiz), between January 2016 and December 2016, because of UGBNPH.

We analysed different variables: gender, age, cardiovascular risk factors such as Arterial Hypertension (AHT), Diabetes Mellitus (DM) and Dyslipidemia (DLP); concomitant treatment with Proton Pump Inhibitors (PPIs), Antiplatelets, Antithrombotics, Nonsteroidal Anti-Inflammatory Drugs (NSAIDs) and Antidepressants; clinical and endoscopic findings; red blood cells and iron requirement, and Helicobacter pylori investigation. We also analysed short and medium term survival rates and recurrence rate in 1-year period.

Results: We included 75 patients admitted because of UGBNPH (56% men), with an average age of 69 years old (men 66, women 74).
We did not find significant differences by gender when analyzing DM (33.3%), with higher frequency of AHT among women (62.5% vs 27.3%) and DLP among men (22.7% vs 0%).
We did not find significant differences by gender when analyzing concomitant treatment with PPIs (43.3%), Antiplatelets (6.7%), Antithrombotics (3.3%), NSAIDs (0%) and Antidepressants (23.2%).

Clinical debut as Hematemesis (66.7%) and Melena (63.3%) was similar in frequency. Regarding Endoscopic findings, in both genders, we found more Esophageal Variceal bleeding as etiology (70%) compared to Portal Hypertension Gastropathy bleeding (33%).

87.5% of admitted patients needed red blood cell transfusion (vs 59.1% of admitted men), with 2.9 packed red blood cells as average (vs 4 packed red blood cells in men). We only began iron therapy in 20% of patients admitted.
Short-term survival rate was 90% (men 86.4%; women 100%) and medium-term survival rate (1 year after admission) was 90%. Bleeding recurrence rate in 1-year period was higher among women (50%) compared to men (36.8%) and related more often to Portal Hypertension Gastropathy (35.8%).

Conclusion: In our research, when analyzing Upper Gastrointestinal Bleeding not associated to Portal Hypertension, cirrhotic men of medium age was the more commonly affected demographic group. Esophageal Variceal bleeding is the most usual etiology in both genders, however Portal Hypertension Gastropathy bleeding has the highest recurrence rate. Regarding red high blood cells transfusion rate we should consider the use of iron therapy in more cases. Finally, short-term prognosis is favorable in our population.

Disclose: Nothing to disclose

P0487 PREDICTOR OF MORTALITY IN UPPER GASTROINTESTINAL BLEEDING IN PATIENTS ALREADY HOSPITALIZED FOR ANOTHER CONDITION: A PROSPECTIVE STUDY
R Jiménez-Rosales, F Vadillo-Calles, E J Ortega-Suazo, J G Martínez-Cara, E Redondo-Cerezo
Virgen de Las Nieves University Hospital, Granada, Spain
Contact E-Mail Address: ritajimenerosales@gmail.com

Introduction: Upper gastrointestinal bleeding (UGIB) is one of the main causes of hospital admission and urgent endoscopy in Gastroenterology departments and represents a true emergency, associated with significant morbidity, mortality and healthcare costs. Several predictors of in-hospital mortality have been identified.

1. We did not find significant differences by gender when analyzing AHT (53.3%), with higher frequency of AHT among women (62.5% vs 27.3%) and DLP among men (22.7% vs 0%).
2. We did not find significant differences by gender when analyzing concomitant treatment with PPIs (43.3%), Antiplatelets (6.7%), Antithrombotics (3.3%), NSAIDs (0%) and Antidepressants (23.2%).
3. Clinical debut as Hematemesis (66.7%) and Melena (63.3%) was similar in frequency. Regarding Endoscopic findings, in both genders, we found more Esophageal Variceal bleeding as etiology (70%) compared to Portal Hypertension Gastropathy bleeding (33%).
4. 87.5% of admitted patients needed red blood cell transfusion (vs 59.1% of admitted men), with 2.9 packed red blood cells as average (vs 4 packed red blood cells in men). We only began iron therapy in 20% of patients admitted. Short-term survival rate was 90% (men 86.4%; women 100%) and medium-term survival rate (1 year after admission) was 90%. Bleeding recurrence rate in 1-year period was higher among women (50%) compared to men (36.8%) and related more often to Portal Hypertension Gastropathy (35.8%).

Conclusion: In our research, when analyzing Upper Gastrointestinal Bleeding not associated to Portal Hypertension, cirrhotic men of medium age was the more commonly affected demographic group. Esophageal Variceal bleeding is the most usual etiology in both genders, however Portal Hypertension Gastropathy bleeding has the highest recurrence rate. Regarding red high blood cells transfusion rate we should consider the use of iron therapy in more cases. Finally, short-term prognosis is favorable in our population.
PATIENTS WHO FAILED INITIAL P0488 RISKS OF UPPER GASTROINTESTINAL BLEEDING IN C.-G Guo1, K.S Cheung1, L Chen1,

Disclosure: Nothing to disclose. More studies in this sense are needed.

bleeding and its management. It is obvious that IPs have poorer outcomes, and management of IPs who develop UGIB have been derived essentially from studies on OPs bleeding, whereas few data are available that focus on in-hospital bleeding and its management. It is obvious that IPs have poorer outcomes, and better understanding of the reasons is essential to develop a specific management. More studies in this sense are needed.

Disclosure: Nothing to disclose.

P0488 RISKS OF UPPER GASTROINTESTINAL BLEEDING IN PATIENTS WHO FAILED INITIAL HELICOBACTER PYLORI ERADICATION THERAPY: A PROBABILITY SCORE MATCHING STUDY
C.-G Guo1, K.S Cheung1, L Chen1, W.K Leung1
1The University of Hong Kong, Department of Medicine, Hong Kong, Hong Kong, China (SAR).

Contact E-Mail Address: waikleung@hku.hk

Introduction: Upper gastrointestinal bleeding (UGIB) is a leading cause of hospitalization which is still associated with significant mortality. Although Helicobacter pylori (HP) eradication and the use of gastroprotective agents could lower the risk of UGIB, the actual bleeding risk in patients who had received HP therapy remains unclear, particularly those who failed initial HP eradication.

Aims and Methods: This was a propensity score matched cohort study to determine the risk of UGIB in HP-infected patients who had received a course of clarithromycin-containing triple therapy for HP eradication between Jan 2003 and Dec 2012. Patients were identified from the territory-wide electronic health database of the Hong Kong Hospital Authority. The follow-up period commenced from 60 days after the HP therapy until the occurrence of UGIB, death or the end of the study (30 Jun 2016). The primary outcome was the occurrence of non-variceal UGIB. Failed initial HP eradication was identified by the need of repeat HP eradication therapy including repeated first-line therapy, a second-line or third-line therapy. Covariates included baseline characteristics, comorbid conditions and concurrent medications. As medication usages could change over time, the follow-up period was split into intervals of 3-month and drug usage was defined in each interval as more than 7 days use. To reduce the indications bias for gastroprotective agents, the last 6-week before the index date of events or censoring were excluded when retrieving proton pump inhibitors (PPI) and histamine type-2 receptor antagonists (H2RA) prescription records. Propensity score (PS) matching was used to select controls for each failed eradication patient by the ratio of 1:5. Cox proportional hazards model was used to adjust the confounders, in which medications were included as time varying variables. Hazards ratios (HR) and corresponding 95% confidence intervals (CI) were presented.

Results: 70,869 patients who had received HP eradication therapy were included in PS matching, with 5,593 patients in the failed initial eradication group and 70,869 patients who had received HP eradication therapy were included. Data collection is still ongoing. A total of 101 internal medicine wards took part in the study. For the purpose of this study, we have identified all possible diagnoses of GIB (upper and lower), describing the length of stay (LOS), mortality rate, and possible risk factors of GIB, including drugs (i.e., anti-platelet agents, anti-coagulants, selective serotonin reuptake inhibitors), smoking habit, alcohol abuse, obesity, index of comorbidity (through the Cumulative Illness Rating Scale [CIRS]), and common chronic diseases (i.e., diabetes mellitus, chronic heart failure, liver cirrhosis, and chronic obstructive pulmonary disease). Odds ratio, 95% confidence interval, and statistical significance were evaluated for all variables.

Results: The REPOSI registry includes 4486 (6-year time span). Among these, at least a diagnosis of GIB was reported in 120 patients (mean age 79.47, F:M 0.9:1), with a crude prevalence of 2.7%. Upper GIB occurred in 72 patients (mean age 79.98, F:M 0.9:1), and both upper/lower GIB in 3 patients. The pooled LOS of patients with GIB was 11.7±8.1 days. 4 patients with GIB died in hospital (3.3%) and eight died within the next 3 months (7.2%). Notably, the use of acetylsalicylic acid (ASA) and anti-coagulants (either vitamin K antagonists and direct oral anti-coagulants) was not associated with GIB (p=ns). Multivariate analysis for all the possible risk factors of GIB is shown in Table. Non-ASA anti-platelet agents (OR 2.77), CIRS index of comorbidity > 3 (OR 2.38), anaemia (OR 2.81), and liver cirrhosis (OR 5.87) were statistically associated with GIB (p < 0.01).

Conclusion: We here show for the first time that a high index of comorbidity (>3) is associated with high odds for GIB. GIB carries both an in-hospital and 3-month high mortality rate. The use of non-ASA anti-platelet agents should be discussed and carefully evaluated in elderly patients.

Disclosure: Nothing to disclose.
Aims and Methods: This study aimed to quantify oesophageal mucosal MCs inclusions and their spacial relationship with allent nerves in reflux disease patients. Distant oesophageal biopsies from 10 patients with ‘true’ NERD and 11 patients with ERD were stained for CGRP and toluidine blue. The position of CGRP positive nerves was determined as number of cell layers from the lumen. Similarly, the number of MCs per high power field (HFP: X50 magnification) and their position in the epithelium was recorded.

Results: The median age was 55.5 years (range: 28–75, 6M:4F) for NERD patients and 59 years (range: 38–75, 7M:4F) for ERD. The median density of MCs/HFP was 0.17 (CI: 0.08–0.5) for ERD vs 0.50 (CI: 0.3–0.8) for ERD (p = 0.01). There was no correlation between oesophageal acid exposure and density of MCs inclusion in NERD (r = 0.09). The MCs were more superficially located (17–25 cell layers) compared to ERD (25 cell layers), p = 0.01. There was no correlation between the position of the MCs and the nerve fibres amongst both groups (r² = 0.2, p = 0.05).

Conclusion: Although there are differences between the density of MCs infiltration and position of the MCs in the epithelium between NERD and ERD, we could not find a good correlation between the position of nerves and the position of the MCs. Therefore, the spacial relationship of the MCs and the mucosal allent nerves in NERD appears to be different to IBS with possible pathophysiological implications.

Introduction: Memantine, currently available for the treatment of Alzheimer’s disease, is an competitive antagonist of the N-methyl-D-aspartate type of glutamate receptors. Under normal physiologic conditions, these unstimulated receptor ion channels are blocked by magnesium ions, which are displaced after agonist-induced depolarization. In humans, memantine administration is associated with different gastrointestinal dysmotility side effects (vomiting, diarrhea, constipation, motor-mediated abdominal pain), thus limiting its clinical use. Memantine treatment of these motility disorders has not been clarified yet. Pigs can be used in various preclinical experiments due to their relatively similar gastrointestinal functions compared to humans.

Aims and Methods: The aim of this study was to evaluate the impact of a single and repeated doses of memantine on porcine gastric myoelectric activity evaluated by means of electrogastrography (EGG). 6 adult female experimental pigs (Sus scrofa f. domestica, mean weight 41±7.5 kg) entered the study for 2 times. The animals received after a single intragastric dose of memantine (20 mg). In the second part, EGG was accomplished after 7 days intragastric administration (20 mg per day). All EGG recordings were performed under general anaesthesia. Basal (15 minutes) and study recordings (120 minutes) were accomplished using an EGG stand (MMS, Enschede, the Netherlands). Running spectral analysis based on Fourier transform was used. Results were expressed as dominant frequency of gastric slow waves (DF) and power analysis (areas of interest).

Results: Single dose of memantine significantly increased DF, from basic values (1.65±1.05 cycles per min.) to 2.86 cpm after 30 min. (p = 0.008), lasting till 75 min. (p = 0.014). Basal power (median 452; inter-quartile range 280–1312 μV²) raised after 15 min. (median 827; IQR 224–2769; p = 0.386; NS), lasting next 30 min. Repetitively administered memantine caused important gastric arrhythmia. Basal DF after single and repeated administration was not different, however, a DF increase in the second part was more prominent (up to 3.18±2.16 after 15 and 30 min, p < 0.001). In comparison with a single dose, basal power was significantly higher after repetitively administered memantine (median 3940; IQR 695–13023 μV²; p < 0.001). Next dose of 20 mg memantine in the second part induced a prominent drop of power after 15 min. (median 541; IQR 328–2280 μV²; p < 0.001), lasting till 120 min. (p < 0.001).

Conclusion: Single and repeated doses of memantine caused gastric arrhythmia and long-lasting low power after repeated administration might explain possible gastric dysmotility side effects in the chronic use of memantine.

Introduction: The relationship between abused women and specific gastrointestinal symptoms has been widely investigated. However, the relationship between abuse and the prevalence of gastrointestinal symptoms and the association with the time of perpetration, type, and severity of abuse is not clear (Y). Most women suffered from childhood and adulthood sexual and physical abuse. In 78% of LC the ASM was < 2 vs 36% of V (ASM > 4 in 54%). Controls lawyers women reported a mean of 4.9 GI symptoms (median 4; IQR 2–8) vs 4.6 of severely abused women (median 4; IQR 2–7). Controls lawyers women with an ASM ≥2 reported significantly more GI symptoms (median 6.5; IQR 3–11 vs median 3; IQR 1–7) (p = 0.002 vs < 2). Severely abused women with an ASM > 3 reported more GI symptoms than those reporting only one type of abuse. Conclusion: Symptoms in abused women mainly concern the abdomen and the GI tract. A history of severe, combined sexual and physical abuse is associated with a higher number of GI symptoms

Introduction: Patients with Amyotrophic lateral Sclerosis (ALS) may be affected by severe dysphagia, emerging in more than 80% of patients during the advanced phases of the disease and can affect all stages of swallowing with the need to resort to enteral nutrition via Percutaneous Endoscopic Gastrostomy. Previous studies have reported oesophageal and gastric dysmotility by manometry, although a large proportion of these patients have been described in small case reports, little is known about alterations of esophageal and gastric motor activity.

Aims and Methods: To assess motor function of esophagus and stomach, 12 ALS patients (4F/8M, age 46±13 yrs), receiving shelter in anti-violence associations and 46 lawyers controls (29–80 yrs), receiving shelter in anti-violence associations and 46 lawyers controls (29–80 yrs), were included as a control group. The severity of abuse was expressed as the Abuse Severity Measure (ASM) (2). The association between abuse characteristics and the number of symptoms, was assessed by Poisson regression model.

Results: In controls lawyers (LC) 65% of women suffered from physical and or sexual abuse in childhood and or adulthood vs 100% of severely abused women (V). Amongst the population, women having suffered from both sexual and physical abuse reported a higher number of GI symptoms than those reporting only one type of abuse. Conclusion: Symptoms in abused women mainly concern the abdomen and the GI tract. A history of severe, combined sexual and physical abuse is associated with a higher number of GI symptoms

Achalasia/Esophagogastric junction dysfunctional motility: a prospective observational trial to validate the utilization of esophageal pressure topography (EPT) as a monitoring tool during esophageal manometry

Aims and Methods: To validate the reliability of esophageal pressure topography (EPT) as a monitoring tool during esophageal manometry. To evaluate the association between EPT and the different manometric patterns of achalasia.

Results: A total of 250 patients were enrolled in the study. The mean age of the patients was 48.2 ± 17.1 years, with 56% being male. The EPT analysis showed a high level of agreement with the conventional manometric patterns of achalasia, with a Cohen's kappa coefficient of 0.85. The EPT analysis was able to accurately identify the presence or absence of concomitant esophageal motility disorders, with a sensitivity and specificity of 91.3% and 96.2%, respectively. The EPT analysis also showed a strong association between the different manometric patterns of achalasia and the presence of concomitant esophageal motility disorders, with a p-value of < 0.001.

Conclusion: EPT is a reliable monitoring tool during esophageal manometry for the diagnosis of concomitant esophageal motility disorders in patients with achalasia. It can be used to accurately identify the presence or absence of concomitant esophageal motility disorders, providing valuable information for the management of these patients.

diagnosed with esophageal spasm during STM (n = 11 [3.0%]) compared to SWS (6/363 [1.7%]). n = 0 [0.0%] and n = 0 [0.0%] respectively. n = 120 (1%). The median procedure time was 48 minutes (18–240). Operative time was significantly less in cases where new triangular knife with water jet was used as compared to those in whom old triangular knife was used (mean, 42.7±4.92 vs 97.0±4.73 min, p < 0.05).

Intra-operative adverse events occurred in 11 (25.6%) children including retro-peritoneal CO2 2, capnoperitoneum 3 and mucosal injury 1. At a median follow-up of 540 days (66–1594), the clinical success was 95.3% (39/41). Clinical success at 1, 2, 3, and 4-years follow-up was 96.4% (27/28), 100% (18/18), 92.3% (12/13), and 83.3% (5/6) respectively. GERD was evident in 55% (11/20) and 53.8% (7/13) children as assessed by endoscopy and 24-hour pH study, respectively.

Conclusion: POEM is safe and effective for the management of achalasia in children. However, GERD is a potential concern and evident in over half of the children. Randomized comparison with Heller’s myotomy combined with fundoplication is warranted in future trials.

Introduction: The relationship between esophageal chemical clearance and abnor-
mal high-resolution manometry (HRM) findings in GERD patients has not been fully in-
terigated in terms of both EGJ barrier and motility function.

Aims and Methods: The main aim of this study was to determine the effect of EGJ barrier and peristaltic dysfunction on esophageal clearance in patients with GERD. 53 patients with PPI-refractory GERD symptoms who underwent both HRM and pH-mi studies were recruited. Two cases of EGJ outflow obstruction were excluded, 51 remaining cases including 4 cases of major motility disorders, 20 cases of minor motility disorders and 27 cases of normal motility were included. Esophageal chemical clearance was evaluated by post reflux swallow-induced peristaltic wave (PSPW) index and mean acid clearance time (MCT) in MI-Hi pH test and compared among different groups of peristalsis and EGJ mor-
phology on HRM. Prediction models were developed to assess the strength of esophageal clearance parameters in GERD diagnosis by calculating the area under the curve (AUC) at receiver-operating-characteristic (ROC) analysis.

Results: The median values of PSPW index for major disorder of peristalsis, minor disorder of peristalsis, and normal peristalsis were 9.4 (1.9–14.7)%, 12.7 (8.6–20.0)% and 16.7 (7.7–30.2)%, respectively. The median values of MACT were 14.2 (2.0–18.0)%, 17.5 (7.7–30.2)%, and 9.4 (1.9–30.2)%, respectively. None of the HRM indices were significantly different between SWS and STM.

Conclusion: Major disorder of peristalsis is a cause of chemical clearance dysfunc-
tion while minor disorder of peristalsis and EGJ morphology type do not play an important role. MACT could be used as a promising index to evaluate chemical clearance in GERD.
Abstract N

P0500 PERORAL ENDOSCOPIC MYOTOMY (POEM) IS EQUALLY EFFECTIVE AND DOES NOT LEAD TO INCREASED ACID REFLUX IN OBESE AS COMPARED TO NON-OBESE PATIENTS WITH ACHALASIA

Introduction: Laparoscopic Heller's myotomy (LHM) is a technically difficult procedure in obese achalasia patients with sub-optimal outcomes and increased rates of gastro-oesophageal reflux disease (GERD). Per oral endoscopic myotomy (POEM) is emerging as a less invasive alternative to LHM in such patients. The impact of obesity on the outcomes and post-treatment GERD after POEM are not well known. Hence our study aims were to compare the outcomes and rates of abnormal oesophageal acid exposure after POEM in obese versus non-obese patients with achalasia.

Aims and Methods: Records of achalasia patients who underwent POEM between April 2014 and June 2017 were reviewed. Patients who underwent pre-treatment timed barium oesophagram (TBE), high-resolution oesophageal manometry (HRM) along with 24-hour post-treatment TBE, pH study and a 24-hour oesophageal pH study were included. Patients were categorized into 2 groups, obese (BMI ≥ 30 kg/m2) or non-obese (BMI < 30 kg/m2). Patient demographics, type of achalasia, prior interventions, pre-treatment and 2-month post-treatment TBE, HRM, Eckhardt’s scores and pH study findings were compared between the 2 groups. Eckhardt’s symptom score of < 3 was considered as successful palliation of symptoms.

Results: Among a total of 134 patients who underwent POEM, 100 patients (Obese = 46; Non-obese = 54) met the study criteria. There were no significant differences in the age, gender, ASA class, achalasia subtype, prior interventions, procedure time, length of stay (LOS) and complication rates between the 2 groups. Post treatment Eckhardt’s scores, HREM parameters and TBE parameters improved significantly in both groups. Eckhardt’s scores improved from an average of 7 to 0 (p < 0.001) in both the groups. However there was no significant difference in pre-post change in values of these parameters between the 2 groups. DeMeester score was abnormal in 57.5% in non-obese versus 43.9% in obese group (p = 0.22). Similarly there was no difference in number of patients who reported having GERD symptoms in non-obese versus obese patients (15.8% vs. 21.1%, p = 0.55).

Conclusion: POEM is an equally safe and effective treatment option for both obese and non-obese achalasia patients. Interestingly, POEM does not lead to increased GERD in obese as compared to non-obese patients. POEM might emerge as the preferred approach for myotomy in obese achalasia patients as compared to LHM in future.[Pre and Post POEM findings in Eckhardt’s score, HREM, TBE and 24-hr oesophageal pH study findings.]

Disclosure: This Abstract is accepted to be presented at Digestive Disease week (DDW) meeting in Washington DC, USA in June/2018.

P0501 ROLE OF HIGH-RESOLUTION MANOMETRY IN THE DIAGNOSTIC AND THERAPEUTIC APPROACH OF POST FUNDOPPLICATION DYSPHAGIA

A Peixoto1, R. Morais1, A. Lasas Gimenez2, T. Perez Fernandez2, S. Casabona Francés2, G. Macedo1, C. Santander Vaqueiro2

1Centro Hospitalar De Sao Joao, Gastroenterology, Porto, Portugal

Contact E-Mail Address: armandoafp5@gmail.com

Introduction: Laparoscopic fundoplication is the gold standard of non-pharmacological treatment of gastroesophageal reflux disease (GERD). Despite good symptomatic control, a significant percentage of patients develop dysphagia at follow-up. High-resolution manometry (HRM) is indicated in the evaluation of these patients, but its impact is not well established.

Aims and Methods: We performed a retrospective study evaluating GERD patients who developed persistent post fundoplication dysphagia. Demographic, clinical and HRM data were evaluated whenever possible in the pre and postoperative period. The analysis of HRM data was performed according to the Chicago III classification.

Results: We included 27 patients, 63% women, with a median age of 58 years (range: 46-64). Nissen fundoplication was the most frequently performed surgical procedure (83%). Patients presented with dysphagia after a median period of 7 months (range: 1-43), more frequently for solid food (59%). 12 patients (44%) had preoperatively HRM, with abnormal findings in half of the cases (ineffective motility n = 4, hypercontractile esophagus n = 2). Significant manometric changes were observed in the postoperative HRM in 16 patients (59%). The main findings were esophagogastric junction outflow obstruction (n = 9, 33%) and absence of contractility (n = 3, 11%). Compared to the preoperative period, there was a significant increase in the resting pressure of the lower esophageal sphincter (8.1 mmHg vs. 20 mmHg, p = 0.043). There were no significant differences in the integrated relaxation pressure (p = 0.686) and in the distal contractile integral (p = 0.109). In patients with available pre and postoperative HRM, the manometric diagnosis was changed in 83% (10/12). In the follow-up, 15% of the patients were submitted to endoscopic dilatation and 41% underwent revision surgery, with clinical success of 25% and 75%, respectively.

Conclusion: HRM in post-fundoplication dysphagia is associated with relevant changes in a considerable percentage of patients, allowing a tailored management approach. Also, this study reflects the need for additional metrics to better identify patients at higher risk for postoperative dysphagia, and potentially benefiting from a different initial therapeutic strategy.

P0502 THERAPEUTIC OUTCOMES FOLLOWING ENDOTherAPY FOR REFRACTORY GASTROPARESIS

University College Hospital, London, United Kingdom

Contact E-Mail Address: kalp.patel42@gmail.com

Introduction: The relative merits of endotherapy for refractory gastroparesis remain unclear.

We assessed the symptomatic response of patients undergoing non-surgical pyloric intervention at a specialist tertiary centre.
Aims and Methods: 57 patients (21 male, mean age 47, 16-81) with medical refractory GERD (28 idiopathic, 29 post-gastric transposition) underwent 117 esophageal treatments from Sep 2013-Sep 2017: each 100IU units of Botex injected into 4 quadrants of the pylorus (N = 66), balloon dilatation to 15-20 mm (EBD, N = 13) or combination therapy (N = 58). Patients with gastroesophageal reflux disease, pyloric surgery or no follow-up were excluded. Symptoms were assessed immediately prior to each procedure and at first follow-up using a retrospective scoring system based on the presence (1 point) or absence (0 points) of Vomiting, Nausea, Bloating or Early satiety. This formulated a composite symptom score (SS) out of 4; positive response was defined by improvement in SS of at least 1. Statistical analysis was performed using Wilcoxon Signed-Rank Test and Fischer's Test.

Results: There were no immediate or late complications. Mean symptom score (SS) improved post-procedure from 2.1 points at baseline to 1.2 post initial endotherapy (p < 0.01) at median follow up of 2.1 months. 20 patients required further endotherapy (median 2.5 treatments; range 2-12); mean SS was 1.0 at latest follow-up.

Per-procedure, mean reduction in SS was 0.8 points (p = 0.01) with overall positive response rate of 67%. By symptom, vomiting was most responsive to EBD (38%, p = 0.02) or combination therapy (66%, p = 0.03). Response to Botex was greater in patients under 40 (83% v 61%, p = 0.04) and females (81% v 33%, p = 0.002). By indication, diabetc GP (N = 17) were most likely to respond (76%).

Sub-group analysis showed procedures for gastroparesis (diabetic/ idiopathic, N = 75) responded significantly more to Botex (mean SS reduction 1.1, p < 0.01) than EBD (mean SS reduction 0.2, p > 0.1) or combination therapy (mean SS reduction 0.44, p = 0.12). Procedures for gastric transposition (N = 42) showed significant improvement post combinations (1.2 v 1.1; p = 0.01) but not post EBD (1.9 v 1.6, p = 0.0) or Botex (1.7 v 1.1, p = 0.08).

Conclusion: Endotherapy is a safe and effective treatment for refractory gastroparesis. We found Botex monotherapy significantly improved symptoms in diabetc or idiopathic gastroparesis, especially younger females; conversely, combination therapy was preferable for delayed gastric emptying post gastroparesis. Careful patient selection may augment therapeutic response.

Introduction: Gastroesophageal reflux disease is diagnosed based on the symptoms such as acid regurgitation or heartburn through transient lower esophageal sphincter (LES) relaxation. Non-erosive reflux disease (NERD) is recognized as hard to treat and less effective with proton pump inhibitor (PPI) compared with erosive reflux disease (GERD). Aims and Methods: A total of 80 patients with NERD were enrolled. All patients underwent esophageal manometry and symptom assessment using symptom index and symptom sensitivity index. All patients received a standard dose of PPI for 4 weeks, and then investigated symptom assessment by questionnaire.

Results: The patients were divided into 2 groups by LES function: normal LES relaxation group (LES relaxation % ≥90%) and abnormal LES relaxation group (LES relaxation % <90%). Clinical and manometric findings were compared and investigated the reponse to PPI. 18 patients (22.5%) were included in the normal LES group whereas 62 patients (77.5%) in LES relaxation abnormality and investigated the reponse to PPI. 18 patients (22.5%) were included in the

Aims and Methods: To clarify the mechanisms of PPI-refractory reflux-related heartburn, as investigated with impedance-pH monitoring. In this prospective, multicenter, pathophysiologic study, 64 patients complaining of heartburn with a negative upper gastrointestinal endoscopy, performed after 4-week PPI withdrawal, and with proven GERD at off-PPI impedance-pH monitoring, entered the study. 32 patients had PPI-refractory heartburn (i.e. < 50% of symptom relief after 8-week high-dosage PPI therapy), and 32 had PPI-responsive heartburn. Mechanisms of heartburn refractoriness to high-dosage PPI were investigated by means of on-therapy impedance-pH monitoring and compared with off-PPI findings. Blindly and manually assessed impedance-pH tracings comprised conventional reflux testing parameters, including esophageal acid exposure time (AET), number of reflux episodes and symptoms association analysis (symptom index, SI, and symptom association probability, SAP), and novel impedance-detected features, including the post-reflux swallow-induced peristaltic wave (PSWP) index and mean nocturnal baseline impedance (MBNII).

Results: The 2 groups were well comparable for gender, age, BMI, rates of hiatal hernia and of abnormal off-PPI impedance-pH variables (p = ns), as shown in the Table. On PPI, median esophageal AET did not differ between the 2 groups. Moreover, AET was abnormal in 6/32 (19%) of PPI-refractory patients. The two groups of reflexes were weakly associated (and had a low p-value), but increased significantly in PPI-responsive cases (p < 0.001). At multivariate logistic regression analysis, only PSWP index was an independent risk factor for PPI refractoriness (OR 1.082, 95% CI 1.022-1.146, p = 0.007). Comparing off- and on-PPI parameters, median PSWP index did not change in PPI-refractory patients (24% vs. 26%, p = 0.327), but increased significantly in PPI-responsive cases (29% vs. 46%, p < 0.001).

Conclusion: Lack of improvement of impaired chemical clearance represents a major biomarker of PPI-refractory reflux-related heartburn. Adjunct therapies aimed to improve chemical clearance by stimulation of timely post-reflux saliva swallowing could benefit patients with PPI-refractory reflux-related heartburn.

Introduction: Heartburn is the most specific symptom of reflux disease, highly responsive to proton pump inhibitor (PPI) therapy. However, some patients do not respond to PPIs, but the mechanisms of refractoriness have not been fully elucidated. Impedance-pH monitoring, allowing a comprehensive off- and on-therapy assessment of reflux, represents a valuable test to investigate PPI-refractoriness.

Aims and Methods: To clarify the mechanisms of PPI-refractory reflux-related heartburn, as investigated with impedance-pH monitoring. In this prospective, multicenter, pathophysiologic study, 64 patients complaining of heartburn with a negative upper gastrointestinal endoscopy, performed after 4-week PPI withdrawal, and with proven GERD at off-PPI impedance-pH monitoring, entered the study. 32 patients had PPI-refractory heartburn (i.e. < 50% of symptom relief after 8-week high-dosage PPI therapy), and 32 had PPI-responsive heartburn. Mechanisms of heartburn refractoriness to high-dosage PPI were investigated by means of on-therapy impedance-pH monitoring and compared with off-PPI findings. Blindly and manually assessed impedance-pH tracings comprised conventional reflux testing parameters, including esophageal acid exposure time (AET), number of reflux episodes and symptoms association analysis (symptom index, SI, and symptom association probability, SAP), and novel impedance-detected features, including the post-reflux swallow-induced peristaltic wave (PSWP) index and mean nocturnal baseline impedance (MBNII).

Results: The 2 groups were well comparable for gender, age, BMI, rates of hiatal hernia and of abnormal off-PPI impedance-pH variables (p = ns), as shown in the Table. On PPI, median esophageal AET did not differ between the 2 groups. Moreover, AET was abnormal in 6/32 (19%) of PPI-refractory patients. The two groups of reflexes were weakly associated (and had a low p-value), but increased significantly in PPI-responsive cases (p < 0.001). At multivariate logistic regression analysis, only PSWP index was an independent risk factor for PPI refractoriness (OR 1.082, 95% CI 1.022-1.146, p = 0.007). Comparing off- and on-PPI parameters, median PSWP index did not change in PPI-refractory patients (24% vs. 26%, p = 0.327), but increased significantly in PPI-responsive cases (29% vs. 46%, p < 0.001).

Conclusion: Lack of improvement of impaired chemical clearance represents a major biomarker of PPI-refractory reflux-related heartburn. Adjunct therapies aimed to improve chemical clearance by stimulation of timely post-reflux saliva swallowing could benefit patients with PPI-refractory reflux-related heartburn.

Introduction: At present time, the spread of the gastroesophageal reflux disease and its morbidity is still on a considerably high level, which compels to searching for new approaches to its diagnostic and treatment.

Aims and Methods: To study the incidence of the virus persistence of the herpes febrilis (HSV), cytomegalovirus (CMV) and human herpes virus type 4 (EBV) in the esophageal mucosa of patients with an erosive form of gastroesophageal reflux disease.

Results: According to the results of the IHC test, 32 patients (42.7%) had a virus infection. The degree of incidence of the virus infection in patients with an erosive esophagitis was the following: 21 patients (40.4%) had herpes febrilis (HSV), 19 patients (36.5%) had cytomegalovirus (CMV) and 12 (23%) patients had human herpes virus type 4 (EBV). 18 patients (35.6%) had a combination of several virus types, from 2 to 3 types simultaneously.

Conclusion: Chronic virus infection of the esophageal mucosa is widespread amongst patients with an erosive form of gastroesophageal reflux disease. In the majority of cases, several virus types are present.

P0511 HEALTH-RELATED QUALITY OF LIFE IMPACT AMONG GASTROESOPHAGEAL REFLUX DISEASE PHENOTYPES IN ECUADORIAN PROTON PUMP INHIBITOR NON-RESPONDERS: A PROSPECTIVE COHORT

Instituto Ecuatoriano de Enfermedades Digestivas (IECED), Guayaquil, Ecuador

Contact E-Mail Address: robertoales@gmail.com

Introduction: More than 50% of Gastroesophageal Reflux Disease (GERD) patients do not respond to Proton Pump Inhibitor (PPI) therapy, rendering them asymptomatic. Yadlapati et al. described the impact on the Health-Related Quality Of Life (HRQOL) doesn’t depend on the GERD phenotype. The Northwestern Esophageal Quality of Life survey (NEQOL), assesses the HRQOL impact across different chronic esophageal diseases (CED). It has previously validated in an Ecuadorian Spanish-speaking population (NEQOL-S). The HRQOL impact among different GERD phenotypes has not been assessed by the NEQOL, especially in a Hispanic population.

Aims and Methods: We aimed to describe the HRQOL impact using NEQOL-S among GERD phenotypes in Ecuadorians PPI non-responders. Prospective cohort study performed at a single medical center from Ecuador (Sept-2016 to Sept-2017). PPI non-responder patients who underwent 24-hour pH-impedance monitoring test and completed the NEQOL-S and SF-12 (a very used survey to assess general-HRQOL in South America). Acid exposure time (AET) and symptoms associations (SRA) were recorded. Participants were classified into cohorts based on test results: GERD (+AET), reflux hypersensitivity (RHS) (-AET/+SRA) and functional heartburn (FH) (+AET/-SRA). The sample size for each group was estimated using known mean PROMIS Global quality of life reported by Yadlapati et al., with an 80% statistical power. The pH-impedance test outcomes and HRQOL results were contrasted between groups through ANOVA or Kruskal-Wallis test. The relationship between HRQOL (NEQOL-S) vs. AET was estimated through Spearman’s rank correlation coefficient (rho). A confirmatory analysis was done using SF-12. A p-value < 0.01 was considered to be statistically significant. Analyses were performed using R v.3.4.2 (R Foundation for Statistical Computing, Vienna, Austria).

Results: There were 85 cases with 24-hours pH-impedance monitoring test performed: 30 (35%) -AET/+AET/+SRA, and 41 (48%) -AET/-SRA. Baseline characteristics and pH-impedance test outcomes are summarized in table 1. NEQOL median scores among groups were: 28.5, 25, 27, respectively (p = 0.719). SF-12 median scores among groups were: 40, 39, 39, respectively (p = 0.977). Relationship between acid exposure time and HRQOL, measured through NEQOL-S and SF-12 reached a rho = 0.90% (p = 0.414) and 7.3% (p = 0.510), respectively.

Conclusion: There is no statistical difference of HRQOL impact among GERD phenotypes, or relationship between HRQOL vs. AET. NEQOL-S results are
Aims and Methods: We aimed to better understand how HRQOL can be affected by different CED in Ecuadorians, through the development of a validated translation of the NEQOL for its use in Spanish-speaking patients. Observational, prospective cohort study (Oct-2016 - Oct-2017). The translation was based on Sperber recommendations. NEQOL-Spanish version (NEQOL-S) and general HRQOL SF-12 survey were prospectively applied to a clinic-based population. NEQOL-S was reapplied 7 days later. The sample size was calculated using estimating proportion formula (5% margin error). Selection criteria: median age 48 (18–90) yo, 242 (63%) female, 24 months median length symptoms. Internal consistency was excellent (CA 0.905). Construct validity did not suggest to reduce survey number of items (KMO = 0.92, p < 0.01). Criterion validity showed good coherence when correlated with the SF-12 survey (rho = 0.57, p < 0.01). Test-retest reliability showed very good correlation when calculated by the intraclass correlation coefficient (ICC) (0.82, p < 0.01). Table 1 resumes how NEQOL-S results differed per CED (p < 0.01).

Aims and Methods: We aimed to evaluate in a population of obese patients candidates to bariatric surgery the agreement in the detection of HH between HRM and intraoperative diagnosis. 52 consecutive morbidly obese patients were prospectively recruited from an outpatient clinic devoted to the surgical therapy of obesity and related disorders. All underwent a preoperative assessment including standardized GERD questionnaire, UGI xray, the ability to diagnose hiatal hernia (HH) is common in obese patients. Classically, HH is detected by upper gastrointestinal endoscopy (UGE) or fluoroscopic upper gastrointestinal (UGI) xray series, however intraoperative diagnosis of HH is considered the gold standard. High resolution manometry (HRM) showed a higher sensitivity and specificity than the classical techniques in non-obese patients. There are no data in morbidly obese population.

Aims and Methods: We aimed to evaluate in a population of obese patients candidates to bariatric surgery the agreement in the detection of HH between HRM and intraoperative diagnosis.

Results: There was a significant correlation between the 3 morphological types of HH assessed by HRM and the presence of HH at UGE (r = 0.28, p = 0.044). 34/52 enrolled patients underwent bariatric surgery; in 9/34 patients HH was intraoperatively diagnosed. The sensitivity of UGI xray or UGI in detecting intraoperative diagnosis of HH was 77.8 % and the specificity was 44%; the positive predictive value was 33.3% and the negative predictive value 84.6%.

sexual partners were at significant risk for Barrett’s dysplasia / esophageal adenocarcinoma (OR, 4.0; 95% CI: 1.2–13.7, p

0.0001), be male (p

0.002). Results: Accuracy, sensitivity, specificity, NPV and PPV for detection were 88.3%, 92.5%, 80%, 84.2% and 90.2% respectively. The percentage of the

system would red-flag the lesion on the endoscopy screen, enabling the endoscopist to take a targeted biopsy. Clinically-inspired CAD systems are therefore shown to be suitable for small and unbalanced databases. The aim of this study was to develop a clinically inspired CAD system using high-quality endoscopic images of BE neoplasia.

Aims and Methods: Endoscopic overview images of 40 subtle early neoplastic BE patients with no suspicion of visible neoplasia and was labeled as the soft spot. The area with ≥1 expert delineations was labelled as the soft spot. The CAD system was trained on low-contrast and texture features (using Gabor filters) of the images, where positive features were taken from the soft spot of the neoplastic images and negative features from the area outside the soft spot and from the NDIBE images. No pre-

processing of the expert delineations prior to input into the algorithm was performed at this stage. Performance was evaluated using a leave-one-out cross validation on a per image basis.

Outcome parameters: 1) Detection scores: diagnostic accuracy of the algorithm per case in terms of accuracy, sensitivity, specificity, NPV and PPV; 2) Localization scores: Percentage of recognized neoplastic images where the delineation of the algorithm detected the soft spot and soft spot.

Results: Accuracy, sensitivity, specificity, NPV and PPV for detection were 88.3%, 92.5%, 80%, 84.2% and 90.2%, respectively. The percentage of the soft- and soft spot that was recognized was 94.6% and 89.2%, respectively.

Conclusion: This CAD system detected early neoplastic BE lesions on endoscopic WLE images with high accuracy, thereby showing feasibility of CAD systems as an important step towards real-time automated detection of early BE neoplasia. Future work will focus on further development of the algorithm towards video analyses and the development of a deep learning algorithm.

Introduction: Early neoplasia in Barrett’s esophagus (BE) is difficult to detect during surveillance endoscopies. This is partly because of its subtle appearance and partly because most endoscopists rarely encounter early BE neoplasia and therefore are unfamiliar with its endoscopic appearance. Computer-aided detection (CAD) systems might assist endoscopists in the recognition of early BE neoplasia, thereby improving efficacy of BE surveillance. Ideally, a CAD system is incorporated in the endoscopy system and would run real-time on the background during surveillance endoscopies. In case a visible lesion is pre-

sent, the CAD system would red-flag the lesion on the endoscopy screen, enabling the endoscopist to take a targeted biopsy. Clinically-inspired CAD systems are therefore shown to be suitable for small and unbalanced databases. The aim of this study was to develop a clinically inspired CAD system using high-quality endoscopic images of BE neoplasia.

Aims and Methods: Endoscopic overview images of 40 subtle early neoplastic BE patients with no suspicion of visible neoplasia and was labeled as the soft spot. The area with ≥1 expert delineations was labelled as the soft spot. The CAD system was trained on low-contrast and texture features (using Gabor filters) of the images, where positive features were taken from the soft spot of the neoplastic images and negative features from the area outside the soft spot and from the NDIBE images. No pre-

processing of the expert delineations prior to input into the algorithm was performed at this stage. Performance was evaluated using a leave-one-out cross validation on a per image basis.

Outcome parameters: 1) Detection scores: diagnostic accuracy of the algorithm per case in terms of accuracy, sensitivity, specificity, NPV and PPV; 2) Localization scores: Percentage of recognized neoplastic images where the delineation of the algorithm detected the soft spot and soft spot.

Results: Accuracy, sensitivity, specificity, NPV and PPV for detection were 88.3%, 92.5%, 80%, 84.2% and 90.2%, respectively. The percentage of the soft- and soft spot that was recognized was 94.6% and 89.2%, respectively.

Conclusion: This CAD system detected early neoplastic BE lesions on endoscopic WLE images with high accuracy, thereby showing feasibility of CAD systems as an important step towards real-time automated detection of early BE neoplasia. Future work will focus on further development of the algorithm towards video analyses and the development of a deep learning algorithm.

Introduction: Volumetric laser endomicroscopy (VLE) provides a circumferential near-microscopic scan of the superficial esophageal wall layers, and has potential
to improve the detection of early Barrett’s esophagus (BE) neoplasia. However, the interpretation of retrieved yellow/grey-shaded VLE images is complex and time-consuming. Artificial intelligence using novel machine and deep learning techniques may aid in this process. Recent studies have focused on neoplasia detection algorithms based on ex-vivo VLE images. Our study is the first to investigate the feasibility of in-vivo BE neoplasia detection using computer-aided detection of VLE images.

Aims and Methods: A prospective single-center study was conducted including 23 Barrett’s patients with and without early neoplasia. High quality in-vivo VLE-histology correlation was provided by laser marking. Laser marked regions of interest consisted of non-dysplastic BE (88 NDVE), and high-grade dysplasia and/or esophageal adenocarcinoma (34 HGD/EAC). Conventional machine learning and recent deep learning techniques were evaluated for the analysis of these regions of interest and differentiate between non-dysplastic and neoplastic tissue. Tissue was first segmented with a pre-trained convolutional neural network (U-net) and clinically inspired features were used for classification between non-dysplastic tissue and neoplasia. Based on earlier findings, analysis was performed on the superficial esophageal wall layers (0.2-1.2 mm), as experiments have demonstrated this generated an optimal classification performance. The reproducibility of the results were independently validated by leave-one-out cross-validation.

Results: In total, 8 different machine learning methods were used for BE neoplasia detection resulting in area under the curves ranging from 0.82-0.90. The clinically derived feature layer histogram in combination with Naive Bayes Classifier demonstrated the most optimal performance. This in-vivo method resulted in an accuracy of 84.4% and an area under the curve of 0.90. Corresponding sensitivity was 73.5% and specificity was 88.6% for the differentiation between 88 NDVE and 34 HGD/EAC VLE images. Negative predictive value and positive predictive value were 89.7% and 71.4%, respectively. Average time for the computer algorithm to analyze a VLE image was 15 milliseconds.

Conclusion: Artificial intelligence, using both machine- and deep learning techniques, correctly identify in-vivo biopsy-correlated VLE images of early BE neoplasia. The clinically derived feature layer histogram shows high detection accuracy. This study shows feasibility of fast and objective computer aided detection, bringing real-time, red-flag identification 1 step closer.

Introduction: Detection and delineation of early neoplasia in Barrett’s esophagus (BE) may be difficult. Blue Light Imaging (BLI; Fujifilm, Tokyo, Japan) is a new optical chromoscopy technique that may improve visualization of these lesions with White Light Endoscopy (WLE). The aim of this study was to evaluate if BLI has additional value in the visualization of early Barrett’s neoplasia. Aims and Methods: In this multicenter prospective cohort study corresponding endoscopic WLE- and BLI images of 40 early neoplastic BE lesions in overview and magnification were obtained in three tertiary referral centers. A proprietary online scoring and delineation module, specifically for this project, was used by 6 international BE experts to assess images in three assessment rounds, each separated by a wash-out period of 2 weeks. Each assessment consisted of overview and magnification images. Assessment 1: WLE images only; Assessment 2: BLI images only; Assessment 3: corresponding WLE- and BLI images in a side-to-side display. The order of images in each assessment round was randomized. During each assessment, the experts scored their appreciation of the macroscopic appearance and surface relief using visual analogue scales (VAS) and subsequently delineated each lesion using the proprietary software tool. Their delineation agreement was quantified by calculating the mean AND/OR ratio for each image in which the AND area was defined as the area delineated by ≥4 experts and the OR area as the area delineated by ≥1 experts. Outcome parameters: 1) Experts’ appreciation of macroscopic appearance and surface relief (VAS-scores); 2) Experts’ ability to delineate the lesion (VAS-scores); 3) Experts’ delineation confidence (VAS-scores); 4) Experts’ quantitative agreement on lesion delineations (AND/OR scores).

Results: Experts appreciated BLI images significantly better than WLE for visualization of macroscopic appearance (median 8.0 vs. 7.0, p < 0.001) and surface relief (8.0 vs. 6.0, p < 0.001). For both overview and magnification images, experts appreciated BLI significantly better than WLE for ability to delineate lesions (8.0 vs. 6.0, p < 0.001 and 8.0 vs 5.0, p < 0.001). There was no overall significant difference in AND/OR scores of WLE-+BLI when compared to WLE, yet agreement increased significantly with WLE-+BLI for cases with a low baseline AND/OR score on WLE, both in overview (mean difference 0.15, p = 0.015) and magnification (mean difference 0.10, p = 0.01).

Conclusion: This study demonstrates the additional value of BLI for the visualization of BE neoplasia. International BE experts appreciated BLI better than WLE for the different aspects of visualization of BE neoplasia and preferred BLI for delineation with the proprietary delineation tool. Their quantitative agreement for delineation increased significantly when BLI was offered next to WLE for lesions that were hard to delineate with WLE alone.

Introduction: The 360 Express RFA balloon catheter (“360 Express”) for radiofrequency ablation (RFA) of Barrett’s esophagus (BE) has the ability to self-adjust to the esophageal lumen ensuring optimal tissue contact during ablation. Aims and Methods: Aim of this randomized clinical trial was to compare three different ablation regimens for treatment of BE using the 360 Express. Patients with a 2-15 cm BE with low-grade dysplasia (LGD), high-grade dysplasia (HGD) or early cancer (EC) were included. Visible lesions were removed by endoscopic resection (ER) prior to RFA. Patients were randomly assigned on a 1:1:1 ratio to the standard (1 x 10J/cm2-clean-1 x 10J/cm2), simple-double (2 x 10J/cm2-no clean), or simple-single ablation regimen (1 x 10J/cm2-no clean). Sample size calculation showed that 36 patients would be necessary in

P0525 EFFICACY OF ARGON PLASMA COAGULATION WITH PRIOR SUBMUCOSAL DISSECTION IN PIGS USING STENT WITH ACELLULAR PORCINE DERMAL MATRIX

S Abiko1, Y Shimizu2, S Ohishi1, T Mizushima1, M Tsuda1, M Ishikawa1, K Mutsuda1, S Miyamoto2, K Yamamoto3, S Ono1, T Kado1, N Sakamoto1

Introduction: Endoscopic resection is regarded as the best treatment for patients with early-stage gastrointestinal cancer. However, argon plasma coagulation (APC) is often selected as a treatment for such patients because of the patient’s general condition or status of the lesions. Recently, we reported good long-term outcomes for patients with esophageal squamous cell carcinoma who underwent APC (local recurrence rate of 3.6% and the 5-year cause-specific survival rate of 100%) in ESGE days 2018. We considered that submucosal injection prior to APC would result in uniform and sufficient coagulation and would contribute to a good outcome. Previously, Manier et al. reported the efficacy of APC with prior submucosal injection (hybrid APC) by using a resorbed porcine esophagus; however, there has been no study using an in vivo model. In this study, we evaluated the efficacy of hybrid APC for the esophagus by using an in vivo porcine model.

Aims and Methods: We performed hybrid APC and direct APC without submucosal injection (standard APC) in various settings. In study 1, we sacrificed the pigs 1 week after APC. In study 2, we sacrificed the pigs 1 week after APC. Pathological evaluation of the depth of coagulation from the basal layer (study 1) and non-atrophic muscle zone (study 2) in the resected specimens was carried out. According to a report by Georg et al., superficial tissue damage of the tunica mucosa was classified as type A damage and an injury pattern limited to the tunica muscularis was classified as type B damage in study 1. The tissue sections were stained with anti-α-SMA antibody, anti-CD107a antibody, anti-CD31 antibody and anti-MPO antibody in study 2. Random submucosal fields from each pig were photographed (high-powered field ≥400) and the stained cells were counted in a blinded manner.

Results: We performed all APC methods using the forced APC mode. Argon gas flow of 2.0 L/min, 5 seconds, at 60 watts (Wt: hybrid APC (types A and B damage) vs standard APC (types A and B damage); 1200 µm (longitudinal muscle layer [ML] and 3090 µm) vs 2750 µm (circumferential muscle layer) and 3340 µm (ML)). Gas flow of 1.0 L/min, 6 seconds, at 40 W: hybrid APC vs standard APC, 70 µm (lumina propria mucosa [LPM]) and 1440 µm (submucosa [SM]) vs 1300 µm (SM) and 2710 µm (ML)). Gas flow of 1.0 L/min, 4 seconds, at 40 W: hybrid APC vs standard APC, 80 µm (LPM) and 1370 µm (SM) vs 630 µm (muscularis mucosa [MM]) and 3010 µm (MM) (NS)). Gas flow of 1.0 L/min, 3 seconds, at 40 W: hybrid APC vs standard APC, 80 µm (LPM) and 870 µm (SM) vs 510 µm (MM) and 2360 µm (ML)). Results (study 2): Gas flow of 2.0 L/min, 3 seconds, at 60 W: hybrid APC (2 lesions) vs standard APC (2 lesions), 23.8 and 2.9 mm² vs 4.5 and 0.0 mm² (NS). Gas flow of 1.0 L/min, 3 seconds, at 40 W: hybrid APC (2 lesions) vs standard APC (2 lesions), 9.6 and 11.2 mm² vs 9.2 and 3.0 mm². Gas flow of 1.0 L/min, 1 second, at 40 W: hybrid APC (2 lesions) vs standard APC (2 lesions), 13.9 and 15.6 mm² vs 6.4 and 7.6 mm². Immunohistochemical analysis demonstrated that the numbers of activated myofibroblasts and infiltrating neutrophils and macrophages were decreased in the hybrid APC group.

Conclusion: Submucosal injection prior to APC contributes to safe and sufficient coagulation for esophageal lesions.

Disclosure: Nothing to disclose.
Disclosure: We hypothesized that a stent covered with acellular matrix of porcine dermis might lead to an earlier re-epithelialization and thus prevent the post-CESD stricture formation.

Aims and Methods: To assess the local effect of a metallic (SEMS) or biodegradable (BD) stent (with or without a acellular matrix) in preventing post-CESD esophageal strictures in pigs. The main outcome was the development of endoscopically non-passable stricture. Secondary outcomes were stricture severity and histopathological parameters. Methods: Pigs were randomized into 6 groups: A. control - CESD only (n = 6); B. CESD + systemic corticosteroids (SC, n = 6); C. BD stent (n = 6); D. SEMS with SC (n = 6); E. SEMS + matrix + SC (n = 8); F. BD stent + matrix + SC (n = 2). CESD was performed by using a dual knife. The acellular matrix was attached to the outer surface of a stent prior to its deployment. SEMS were removed 21 days after CESD. Pigs were sacrificed if a stricture developed.

Results: A total of 33 pigs underwent CESD in the middle esophagus; the average length of the defect was 5.5 ± 0.3 cm. All pigs with BD stent experienced macroscopic inflammation, massive hypergranulation and food stagnation within the stenosis, which were BH and biopsies. Thus, we decided to stop using the HD stent prematurely and BD groups were excluded from the final analysis. Significant strictures were developed in all pigs except 1 (group B - SC) after a mean of 12.9 ± 0.1 days from CESD (groups A and B) and in 13.9 ± 1.4 days after SEMS extraction (groups C and D). The longest stricture was observed in the group A (2.7 ± 1.3 cm) and the shortest in SEMS groups (C, D) (1.5 ± 0.8 cm and 1.6 ± 1.1 cm). The narrowest stricture occurred in groups A and C (0.5 ± 0.3 mm and 8.8 ± 3.7 mm) vs. groups B and D (14.4 ± 1.1 mm and 13.6 ± 7.7 mm). (p < 0.05).

Re-epithelialization was present in 80% of animals in the group A, in all animals in group D. The widest re-epithelization layer (0.14 mm) was present in the group D. The re-epithelization was present in 80% of animals in the group A, in all animals in group B, in 42% of animals in the group C and in 71% of animals in group D. The re-epithelization layer (0.14 mm) was present in the group D. The re-epithelization layer (0.14 mm) was present in the group D.

Conclusion: None of the tested methods resulted in the effective prevention of post-CESD esophageal stricture. Coverage of SEMS using acellular matrix of porcine dermis resulted in a decrease in the severity of stenosis and improved post-CESD esophageal stricture formation. The BD stent is inappropiate in this indication.

Introduction: The link between inflammation and cancer is well established. Esophageal carcinogenesis is an ideal model to study the underlying mechanisms of inflammation induced tumor initiation: Chronic inflammation induces Barrett’s Esophagus (BE) which later advances to esophageal adenocarcinoma (EAC). Inflammation at the level of HHV, a downstream target of NF-kB, have been identified as an important mediator of tumorigenesis in the IL-1β mouse model of EAC. To analyze the effect of Nfkb signaling in MFs, we investigated by cytokine array and qPCR analysis. To combine readily identifiable risk factors, risk prediction modelling is a promising tool for selecting individuals with high absolute cancer risk. This study aimed to develop a OSCC risk prediction model for individuals.

Methods: In this retrospective study, we analyzed the interaction of epithelial and stromal cells in 3D organotypic cultures of mouse and human BE organoids.

Results: Histological scoring of IL-1β. Vimm-Cre (p56Cre)1 mice showed a significantly attenuated phenotype compared to IL-1β mice, with mild inflammation, decreased proliferation and crypt fission and increased differentiation in the junctional region at the gastric cardia where metaplasia and dysplasia would arise in IL-1β. Vimm-Cre(p56Cre)1 mice were identified as a model of inflammation induced tumorigenesis in the IL-1β mouse model of EAC. The IL-1β mouse model of BE and EAC, IL-1β induces chronic inflammatory and spontaneous carcinogenesis in an IL-6 dependent manner. This inflammatory milieu often occurs apart from cancer cells and infiltrating immune cells, myofibroblasts (MF) that express uSMA and Vimentin. In the L2-IL-1β mouse model increased inflammation correlates with increased MFs and an accelerated phenotype.

Conclusion: In summary, we have analysed the role of fibroblasts in an inflammatory environment and conclude that NFKb in the stromal cells is an important driver of esophageal carcinogenesis. This also suggests that inhibition of NFKb signaling in general or NIK specifically could be an important treatment strategy to prevent tumor progression during surveillance of BE patients.

Introduction: The esophageal gland duct may serve as a pathway for the spread of early esophageal squamous cell neoplasia (ESCN) to a deeper layer. However, the incidence of ductal invasion and the complete endoscopic submucosal dissection (ESD) has yet to be investigated.

Aims and Methods: We consecutively enrolled patients with early ESCN who were treated with ESD. The resected specimens were retrospectively reviewed for the number, morphology, resected margin, distribution and extension level of DI, which were then correlated to clinical factors and survival.

Results: A total of 160 lesions were analyzed, with en bloc and R0 resection rates of 97.5% and 95.6%, respectively. A total of 317 DIs (median: 3 range 1–40 per lesion) in 61 lesions (38.1%) were identified. Of these lesions, 14 have DIs maximally extended to the level of lamina propria mucosa, 17 to muscularis mucosae, and 30 to the submucosal layer. Multivariate logistic regression analysis showed that ESCN located in the upper esophagus (OR = 2.93, 95% CI, 1.02–9.42), large tumor circumferential extension (OR = 5.39, 95% CI, 1.06–27.47), deep tumor invasion depth (OR = 4.12, 95% CI, 1.81–9.33) and numerous Lugol-voiding lesions in background esophageal mucosa (OR = 2.65, 95% CI, 1.10–6.37) are risk factors for esophageal DI. The maximally extended level and total number of ducts involved were significantly correlated with the depth of cancer invasion (p < 0.05). The patients with DI had worse overall survival (log-rank p = 0.015) and recurrence-free survival (log-rank p = 0.02) than those without DI at successful ESD.

Conclusion: DI is not uncommon in early ESCN. Our findings may guide clinical decision making with regards to endoscopic treatment and surveillance.

Disclosure: Nothing to disclose.

Introduction: Oesophageal squamous cell carcinoma (OSCC) is the dominant histological subtype of oesophageal cancer in Eastern countries and globally, and is associated with an increasing incidence of oesophageal adenocarcinoma in Western countries. OSCC remains a major type of oesophageal cancer also in these countries. In 2012, approximately 38,000 new cases of OSCC occurred in Europe, North America, and Oceania, accounting for around 60% of all cases of oesophageal cancer in these regions. OSCC is characterized by poor prognosis with a population-based overall 5-year survival rate of less than 20%, which has not improved much in recent years. Upper endoscopy for OSCC may be indicated to detect disease at curable stage, but universal endoscopic screening is not justified given the low absolute risk of OSCC in the population. A more feasible way may be to identify a limited group of individuals with high absolute risk of OSCC, who might benefit from tailored endoscopic screening and surveillance.

Aims and Methods: By combining readily identifiable risk factors, risk prediction modelling is a promising tool for selecting individuals with high absolute cancer risk. This study aimed to develop an OSCC risk prediction model for individuals.

Methods: This was a nationwide Swedish population-based case-control study, including 167 new cases of OSCC and 820 randomly selected control participants. Associations between candidate predictors and risk of OSCC were assessed using multivariable unconditional logistic regression, producing odds ratios with 95% confidence intervals (CI). The discriminative accuracy of the model was assessed by the area under the receiver operating characteristic curve (AUC) and the net reclassification improvement (NRI) by cross-validation. Models for projecting individuals’ absolute 5-year risk of OSCC were developed by incorporating the age- and sex-specific incidence rates of OSCC and competing risk of death from other causes.

Results: A model including age, sex, tobacco smoking, alcohol consumption, associations with living in a partner, and place of residence during child hood generated an AUC of 0.81 (95% CI 0.77–0.84). A model based only on age, sex, tobacco smoking, and alcohol consumption reached a similar AUC (0.79, 95% CI 0.75–0.82). The estimated individuals’ absolute 5-year risk of OSCC varied according to combinations of risk factors. Individuals’ absolute risk assessment was available in an excel calculator.

Conclusion: To the best of our knowledge, this is the first study that developed a prediction model for the absolute risk of OSCC in a Western population. This
P0527 DURABILITY OF RADIOFREQUENCY ABLATION FOR TREATMENT OF ESOPHAGEAL SQUAMOUS CELL NEOPLASIA: 5 YEAR FOLLOW-UP OF A PROSPECTIVE STUDY IN CHINA

Introduction: Radiofrequency ablation (RFA) is an accepted treatment modality for early Barrett’s neoplasia. Less is known about RFA for esophageal squamous cell neoplasia (ESCN). Our group has reported several prospective studies of RFA for ESCN in high-risk areas in China. Complete remission (CR) of ESCN was achieved in up to 87% of patients, but follow-up (FU) was restricted to 12 months.1-5

Aims and Methods: We aimed to evaluate long-term 5 year outcomes after RFA for ESCN. Patients with flat type (Paris 0-IIb) unstained lesions (USLs) on Lugol’s endoscopy, 3-12cm in length and with moderate or high grade intraepithelial neoplasia (MGIN,HGIN) or mucosal squamous cell cancer (ESCC-m) were treated with RFA every 3 months in the first year, until CR (defined as absence of MGIN or worse in biopsies) was established. All patients with CR at 12 months (CR12) were included in the current study extension, and underwent annual FU endoscopy with Lugol’s and biopsies. Flat type USLs were treated with RFA; other lesions were treated per investigator’s discretion. We also describe the clinical course of patients with persistent ESCN at 12 months (treatment failures), with treatment and FU per investigator’s discretion.

Results: The 78 patients with CR12 were included in this extension. During a median follow-up of 48 months (IQR 48-48) with 5 endoscopies (IQR 4-6) after the first year, 67/78 patients (86%) sustained CR. Recurrence occurred in 7 pts (9%); MGIN:6, HGIN:1 and all were managed with RFA. CR was re-established in 4, and 3 pts were treated at the last endoscopy. 4 other pts (5%) had progression (non-flattened HGIN; ESCC-sm-3) and were managed endoscopically with ESD. During FU, protocol violations (prolonged intervals, USLs left untreated or no adequate FU after retreatment) occurred in 46/78 patients (59%). Of the 12 treatment failures at 12 months, progression of ESCN occurred in 6 (50%), managed by endoscopic (1) or non-endoscopic (5) treatment. Overall, 2 patients developed subepithelial disease that was not clearly visible with Lugol’s endoscopy. Post-hoc analysis on the ‘pink-color sign’ at baseline, showed that the observed pink-color change after Lugol’s staining significantly predicted recurrence or progression during FU as well as initial failure at 12 months (HR 4.0, 95% CI 1.8-9.2).

Conclusion: RFA is relatively easy to apply and can efficiently treat large areas with ESCN. Despite protocol violations that may have interfered with the efficacy of RFA treatment in 59% of patients, the great majority with CR12 had sustained CR during FU. However, some patients progressed to advanced disease and 2 patients developed subepithelial disease that was not visible with Lugol’s. Based on currently available data, we advise to restrict the use of RFA for flat type MGIN and HGIN without pink-color sign on Lugol’s chromoscopy.

P0528 CHEMORADIOThERAPY FOR LYMPH NODES RECURRENT AFTER ESOPHAGECTOMY FOR ESOPHAGEAL CANCER

S Matono, T Tanaka, N Morii, H Hino, K Saisho, Y Akagi
Kurume University School of Medicine, Dept. of Surgery, Kurume, Japan

Contact E-Mail Address: mls0805@med.kurume-u.ac.jp

Introduction: Recurrent esophageal cancer after esophagectomy has a poor prognosis, while we sometimes encounter patients with long-term survival. Lymph node recurrence is one of the common recurrence patterns after esophagectomy. Here we discuss the usefulness of chemoradiotherapy for lymph nodes recurrence after esophagectomy.

Aims and Methods: The aim of this study is to evaluate outcomes of chemoradiotherapy and prognostic factors for patients with only lymph nodes recurrence. Four hundred six patients underwent R0 esophagectomy for thoracic esophageal squamous cell carcinoma at our institution, between 1995 and 2014. Recurrence occurred in 148 patients (36%). Among these, 38 patients (39%) developed recurrence only in the lymph nodes. The median follow-up duration after recurrence was 13 months (range from 1 to 155 months). Post-recurrence survival was defined as the time between the first recurrence and death or most recent follow-up examination.

Results: The 58 patients with lymph node recurrence were 54 males and 4 females, with a median age of 64 years (range from 44 to 80 years). Of those, 16 (28 %) had pT1 cancer, 8 (14%) had pT2 cancer, 31 (53%) had pT3 cancer, and 3 (5%) had pT4 cancer. The number of patients at pN stage (UICC 7th) was 3/N1/N2/N3 was 16 (28%): 14 (24%): 19 (33%): 9 (16%), respectively. 11 patients (19%) had pM1 LYM. 3-field lymphadenectomy had been performed in 33 (58%) patients, and 2 or less-field lymphadenectomy was performed in 25 (42%) patients. The median time to recurrence after esophagectomy was 12.5 months (range from 1.8 to 47.5 months). M1 LYM recurrence occurred in 28 patients (48%) including 15 patients with both M1 LYM and regional lymph node recurrence, and 30 patients (52%) had only-regional lymph node recurrence. 34 patients (59%) had one single site of lymph node recurrence, and 24 patients (41%) had two or more recurrence sites. 43 patients (74%) had 1-field recurrence, and 15 patients (26%) had 2-field recurrence. Chemoradiotherapy was employed in 36 patients including 8 patients with surgery. The remaining 22 patients received other treatments including chemotherapy, radiotherapy, surgery, or best supportive care. The overall 1- and 3-year-survival rates in all patients after recurrence were 55% and 22%, respectively. By univariate analysis, the depth of tumor invasion (pT), the interval until recurrence, and the method of treatment were each found to be a factor affecting survival (p <0.05). The location and number of lymph nodes recurrence did not significantly affect survival. In multivariate analysis, the depth of tumor invasion (pT1,T2 vs. pT3,T4; hazard ratio 0.407; 95% confidence interval 0.212-0.754; p =0.004) and treatment (chemoradiotherapy vs. other treatment: hazard ratio 0.427; 95% confidence interval 0.234-0.786; p=0.008) were found to be an independent prognostic factor. The 3-year-survival rate in patients with pT1,T2 was 36%, compared to 12% in those with pT3,T4 (p=0.0014). The 3-year-survival rate in patients who received chemoradiotherapy was 29%, compared to 7% in those who received other therapy (p=0.0030).

Conclusion: Our findings suggested that chemoradiotherapy could improve survival in those esophageal squamous cell carcinoma patients with only lymph nodes recurrence. The location and number of lymph nodes recurrence did not affect survival.

Introduction: Globally, 80% of all esophageal cancer cases are esophageal squamous cell cancer (ESCC), arising from esophageal squamous cell neoplasia (ESCN). Patients with ESCC have poor prognosis, but when diagnosed at the stage of ESCN, curative endoscopic treatment can be performed. ESCN mainly occurs in developing countries like Central and Eastern Asia and Eastern and
Southern Africa, often with limited endoscopic expertise and resources. Hence, an easy-to-use, low-cost treatment for ESCN would be of great value. Focal Cryoballoon Ablation therapy (FCBA) (C2 Therapeutics Inc. Redwood City, CA, USA) is a novel endoscopic ablation therapy that comprises a through-the-scope catheter with a conformable balloon that obviates the need for side-by-side inflation of disposable oxygen cartridges. The balloon is simultane-ously inflated and cooled with nitrous oxide from the cartridge, resulting in ice patches of approximately 2cm. FCBA is handheld, easy to use and requires no capital equipment. Although early studies for FCBA of Barrett’s esophagus have shown promising results, limited data are available for its use in ESCN.

Aims and Methods: We aimed to assess the safety, tolerability and efficacy of FCBA in the eradication of ESCN. In this single-center prospective trial in China, patients with a flat type (Paris 0-IIb) unstrained lesion (USL) on Lugol’s chromostaining were enrolled. Escape lesions were selected. A diagnosis of Moderate or High Grade Intraepithelial Neoplasia (MGIN/ HGIN) were enrolled. At baseline, the entire USL was ablated with side-by-side ablations of 10 seconds and tattoos were placed to identify the treatment area (TA). Ablation was performed at the TA. A second treatment was repeated within 3 months in the case of persisting USLs. All patients underwent a 12-month endoscopy with biopsies from the TA. Outcomes included safety, tolerability (11-point visual analog scale (VAS) for pain); complete response (CR; absence of MGIN or worse in all TA biopsies) rates at 3 and 12 months; and adverse events.

Results: We enrolled 80 patients (59 MGIN, 21 HGIN) with a median USL length of 3 (IQR 3–4) cm. MGIN and HGIN (IQR 4–7) side-by-side ablations were performed per patient over a median ablation time of 8 (IQR 5–10) minutes. After a single treatment, 70/78 patients (90%, per protocol) exhibited CR. The other 8 patients had residual USL and were retreated; all had CR 3 months later (45). A total of 7 patients were lost to follow-up. At 12 months, 76/78 patients (97%, per protocol) or 76/80 (95%, intention to treat) patients exhibited CR. AT 12 months, 2 patients, both with MGIN at baseline, were found to have a USL with MGIN. No strictures or serious adverse event had been noted. 3 patients developed self-limiting mucosal lacerations upon balloon inflation. Post-procedure median VAS was 1 (IQR 0–2) at day 2, and 0 (0–0) at days 7 and 30. Median dysphagia score was 0 (0–0) on all days.

Conclusion: Results of our prospective cohort study in China suggest that focal cryoablation in endoscopic squamous cell carcinoma is safe, well tolerated, and highly effective in inducing endoscopic and histological remission. FCBA is a promising, easy to use and low-cost modality for the treatment of ESCN.

Disclosure: This study was financially supported by C2 Therapeutics, Inc.
resorption. However, there are rarely published studies investigating the clinicopathologic characteristics of synchronous multiple early esophageal neoplastic lesions so that clinicians can make better decisions for the preserved esophagus after endoscopic treatment.

Aims and Methods: The clinical data of 37 patients with synchronous multiple early esophageal neoplastic lesions who meet the inclusion criteria between May 2013 to May 2017 were analyzed. According to postoperative pathological results, patients were divided into 2 groups: Group A: all the lesions had confirmed histopathology and clinical neoplastic (EGJ) or esophageal cancer; Group B: only 1 lesion had confirmed HGIN or esophageal cancer, while other lesions were high-grade intraepithelial neoplasia (HGIN). The clinicopathologic features were compared between the 2 groups by univariate analysis.

Results: There were 20 patients, 44 lesions in group A and 17 patients, 34 lesions in group B. No significant differences were observed between the 2 groups in terms of age, gender, body mass index (BMI), family esophageal cancer history, heavy drinking, heavy smoking, flush after drinking, while significant differences were found between the 2 groups in avoiding lesions (LVLAs) grade (p = 0.001), submucosal involvement on EUS (p = 0.005), circumferential extent (p = 0.000), R0 resection rate (p = 0.007), lesion size (p = 0.000) and pathological upgrade rate (p = 0.043).

Conclusion: The mean grade of LVLAs larger, lesion size, circumferential extent ≥ 1/2, non-R0 resection, postoperative pathological estimation upgrade, and an EUS finding of submucosal involvement are considered high-risk factors in patients with synchronous multiple esophageal neoplastic lesions. Therefore, clinicians must remain vigilant and perform careful observations and surveillances on patients with such characteristics during endoscopic examination.

Introduction: Over 5 years in Japan, DOACs replaced direct oral anticoagulants (DOACs) was released in Japan. It was not just known that DOACs have similar efficacy as vitamin K antagonists (VKA), but might be a more mucosal-friendly agent than VKA[1]. However, for reducing the incidence of mucosal injuries, we don’t know what kind of agents is helpful to use concomitantly for patients taking DOACs as well as VKA.

Aims and Methods: The aim of this study is to explore whether proton pump inhibitor (PPI) play a protective role for gastric mucosa in patients taking DOACs or VKA. To reveal the role of PPI, we compared the severity of gastric mucosal injury between PPI users and nonusers in the subjects taking DOACs or VKA, individually. Data were extracted from the records of subjects who underwent upper gastrointestinal endoscopy at our department between April 2015 and December 2017. Of the 3,900 subjects analyzed, we focused on 203 subjects who took DOACs (Dabigatran, Edoxaban, Rivaroxaban, Apixaban) or VKA (Warfarin). After excluding subjects who took other type of antacid (histamine 2 receptor blockers or potassium-competitive acid blockers) in each group, we divided subjects into 2 subgroups: those who were taking PPI, and those who were taking no antacids. Severity of gastric mucosal injury was evaluated endoscopically according to the modified LANZA score (MLS) [2]. Statistical analyses were performed by Fisher’s exact test.

Results: This study included 88 subjects in DOACs users (62 men, 26 women; mean age 72.9 years; 58 PPI user, 30 nonuser) and 72 subjects in VKA users (45 men, 27 women; mean age 74.9 years; 49 PPI user, 23 nonuser). In patients taking DOACs, average MLS of PPI users and nonusers was, respectively, 0.24±0.76 and 0.63±1.45 (p = 0.263). In patients taking VKA, average MLS of PPI users and nonusers was, respectively, 0.59±1.38 and 1.91±2.25 (p = 0.045). In the subjects taking VKA, gastric mucosal injury was statistically significantly mild in PPI users but not in the subgroup taking DOACs.

Conclusion: PPI play a protective role in gastric mucosa in patients taking VKA but not in patients taking DOACs.

Contact E-Mail Address: d.kurguzova@mail.ru

Introduction: Among the reasons for proton pump inhibitor (PPI) resistance is different quality of enteric coatings, as a result of which PPIs acid degradation in the stomach leads to its release there. The influence of factors such as pathologic duodenogastrectomy reflux (PDGR) with pH ≥ 7 followed by its decrease and the pH increasing ≥ 4 within multiple PPIs dosing in patients with gastro-esophageal reflux disease (GERD) on coatings and premature active compounds degradation has not been studied specifically. PDGR and pharmacological acid suppression can be reliably modeled with comparative dissolution testing (CDT). In PDGR, pH ≥ 7 exposure time for omeprazole and rabeprazole is 4 and 12 minutes respectively. Omeprazole or rabeprazole detection in the pH 7 buffer after 4 or 12-minute exposure should be estimated as PPIs degradation in the stomach due to PDGR. The stability of PPIs in case of an inhibited gastric acid secretion can be confirmed by drug compounds absence in the pH 4 buffer

Aims and Methods: CDT (pH 7.0±0.05, pH 0.1±0.05) has been used to simulate influence of PDGR and pharmacological acid suppression on omeprazole and rabeprazole gastric release and degradation. The additional aliquots were taken from the pH 7.0±0.05 solution after 4 minutes for original omeprazole (O0) and geneties (GO), G02, GO3 and 12 minutes for rabeprazole (OR, GR1, GR2). PDGR resistance for PPIs capsules and tablets was determined by active substances presence or absence.
Results: The drug release was not detected in the pH 1.2 buffer. Drugs were moved for pH 1.2±0.05 to pH 7.0±0.05. The drug release in the pH 7.0±0.05 after 4-minute exposure was 4.7±0.07%, 0.8±0.5±6%, 82.5±1.7% for OO, GO1, GO2, GO3, respectively. OR and generics were subjected to the same conditions during 12 minutes with only OR1 detected final release (5.4±0.4%). Therefore, PDGR model demonstrated poor reflux influence on OO and GR1, strong influence on GO2 and GO3 with the almost complete omeprozole release and its potential degradation after following pH decrease. Any omeprozole was not detected in the pH 4.0±0.05. Pellet destructions were not registered for GO1 and GO3 while GO2 pellets were totally degraded. Non-degraded pellets were moved to pH 7.0±0.05 where their release was determined. In the same dissolution conditions, rabeprazole amount from GR2 after 10-, 15-, 20-, 30-, 45-, 60 minutes was 0; 0; 5.5±0.4%; 38.8±0.4%; 58.0±0.3%; 82.4±0.5%; 68.9±0.5%. No OR and GR1 release or visible tablets destruction were registered. Pharmacological acid suppression model had demonstrated OO, OR, GO1, GO3 and GR1 resistance while total GO2 and partial GR2 degradation were determined.

Conclusion: Omeprazole and rabeprazole generics with high-risk degradation under PDGR and multiple PPIs dosing were determined by CDT. Omeprazole was totally degraded in pH 4.0±0.05 but not rabeprazole.

Disclosure: Nothing to disclose

P0537 LONG-TERM OUTCOMES AND PROGNOSTIC FACTORS OF NON-CURATIVE ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC CANCER IN ELDERLY PATIENTS

Y Toyama1, M Endo1,2, S Nakamura1, R Akasaka1, S Yama1, K Kawakusa1, M Eizu2, N Uesugi1, T Sugai1, T Matsumoto1
1Iwate Medical University, Division of Gastroenterology, Department of Internal Medicine, Morioka, Japan
2Kainanbushi Endoscopy Clinic, Morioka, Japan

Introduction: Gastric cancer is still one of the leading causes of cancer-related death in Japan. Due to wide spread use of endoscopic submucosal dissection (ESD), physicians are facing dilemma as to the indication for additional gastrectomy in elderly treated for curative ESD. This is due to little information with regards to the long-term outcomes and prognostic factors of non-curative ESD for gastric cancer in elderly patients.

Aims and Methods: We aimed to clarify the long-term outcomes and prognostic factors of non-curative ESD for gastric cancer in elderly patients. Among 1,358 patients with early gastric cancer (EGC) treated by ESD at our institution during 2002-2012, we enrolled 87 patients with age ≥75 yrs, who were treated by non-curative ESD. First, clinicopathological findings and long-term outcomes up to the end of 2017 were evaluated. Next, the prognostic factors were analyzed using the Kaplan-Meier methods and a Cox proportional hazards model.

Results: 27 of 87 patients died of any cause. However, only 1 patient died of gastric cancer. 3-year overall survival (OS) and 5-year OS were 89.7% and 79.3%, respectively. The univariate analyses revealed that patients who were in Eastern Cooperative Oncology performance status of 2 or 3, high Charlson comorbidity index (CCI) (>3), high neutrophil to lymphocyte ratio (>3.3), low prognostic nutritional index (< 44.8), antral location of EGC and depressed or completely flat configuration of EGC were factors associated with death. The high CCI (>3) was found to be an independent prognostic factor associated with OS (hazard ratio: 2.79, 95%CI: 1.16–6.69, p = 0.021).

Conclusion: After non-curative ESD for gastric cancer in elderly, CCI may be a clue for decision making of additional gastrectomy. Careful follow up without additional gastrectomy may be an acceptable strategy for elderly patients.

Disclosure: Nothing to disclose
submucosa using distal hood of the endoscope. We hypothesized time to flap formation would be a surrogate endpoint for technical success for duodenal ESD.

Aims and Methods: The aim of this study was to assess the feasibility of time to flap formation as endpoint for duodenal ESD. This was a retrospective observational study from a university hospital. A total of 102 cases that underwent ESD for duodenal superficial neoplasia from July 2013 to June 2017 were included in this study. ESD was performed using DualKnife J ( Olympus medical systems, Tokyo, Japan) and short tip type transparent hood (ST hood, FUJIFILM Medical Co., Ltd. Tokyo, Japan). An endoscopist reviewed all movies of the procedures and measured time to flap formation and total procedure time. In this study, flap formation was defined as the timing when complete exposure of submucosa using upper rim of the hood was obtained. The distribution of total procedure time and time to flap formation was analyzed in addition to other short-term outcomes. Those were compared according to the skill level of endoscopists (expert: >100 duodenal ESD, and the others). Moreover, we analyzed the linear regression between total procedure time and time to flap formation and other clinical features of the lesion using least square methods.

Results: As for location of the lesion, 13.7% located in bulbs, 73.5% in descending part, 3.0% in horizontal part, and 9.8% located in superior duodenal angle (SDA) or inferior duodenal angle (IDA). The mean lesion diameter was 32.5±10.5 mm. Resection in a submucosa and R0 resection was 98.3%, respectively. Bleeding and perforation was found in 3.0% and 5.9% of patients, respectively. Mean procedure time was 55.8±3.9 min and mean time to flap formation was 13.5±1.1 min. It was significantly shorter by expert’s hand (12.1±1.1 min vs 24.0±2.9 min, p<0.0001). Multiple linear regression analysis revealed time to flap formation as well as lesion size, location, and endoscopists’ skill were independently correlated with total procedure time (Table 1). Complete formation reflected the skill level of the endoscopists and predicted total procedure time independently of the size and the location of the lesion. It could be a surrogate endpoint for technical success of duodenal ESD.

P0540 EFFECT OF THE DURATION TIME OF UPPER GASTROINTESTINAL ENDOSCOPY ON THE DETECTION RATE OF GASTRIC NEOPLASTIC LESIONS

St. Marianna University. School of Medicine. Gastroenterology and Hepatology, Kawasaki, Japan

Contact E-Mail Address: y2sato@ marianna-u.ac.jp

Introduction: Early detection and prompt treatment using upper gastrointestinal endoscopy are important to reduce the mortality rates of gastric cancer. Previous reports on esophagogastroduodenoscopies (EGD) have stated that compared to normal screening EGD, it is thought that the detection of gastric neoplastic lesions is made possible using a short examination time and efficient biopsies due to an increase in the accumulation of experience.

Results: From June 2017 to December 2017, we investigated 1019 patients (501 men and 518 women, mean age: 62.8±16 years) who underwent a first screening EGD at our hospital. EGD was performed using DualKnife J (Olympus medical systems, Tokyo, Japan) and short tip type transparent hood (ST hood, FUJIFILM Medical Co., Ltd. Tokyo, Japan). An endoscopist reviewed all movies of the procedures and measured time to flap formation and total procedure time. In this study, flap formation was defined as the timing when complete exposure of submucosa using upper rim of the hood was obtained. The distribution of total procedure time and time to flap formation was analyzed in addition to other short-term outcomes. Those were compared according to the skill level of endoscopists (expert: >100 duodenal ESD, and the others). P0541 VALIDITY OF SUBMUCOSAL PATTERN ANALYSIS OF EUS FOR PREDICTING DEPTH OF INVASION IN ULCERATIVE EARLY GASTRIC CANCER

J.H Kim
Seoul National University Busan Paik Hospital, Busan, Korea (Republic of)

Contact E-Mail Address: zep2000@hanafos.com

Introduction: Accuracy of endoscopic ultrasonography (EUS) for predicting depth of invasion in early gastric cancer (EGC) accompanied with endoscopic ulcer or ulcer scar was lower than that without ulcer.

Aims and Methods: We tried to evaluate the validity of submucosal pattern analysis of EUS for predicting depth of invasion in ulcerative EGC. Demographic, endoscopic and EUS features of 176 consecutive endoscopically suspected EGC patients who underwent the EUS examination and the endoscopic or surgery retrospectively reviewed. The EUS findings were classified as the (1) no deformity type, (2) fan-shaped deformity type, and (3) arch-shaped or punch-shaped deformity type, according to submucosal layer change. The EUS findings also classified into 2 groups; submucosal fibrosis and no fibrosis groups.

Results: 73 among total 176 cases (41.5%) were accompanied with the active or healing staged endoscopic ulcer, whereas SI-staged ulcer was found in 62 cases (35.2%) and no ulcer group was 41 cases. The EUS fibrosis was combined in 71 cases (40.4%), Fan-shaped deformity type, and arch-shaped deformity. The histologic submucosal fibrosis was found more frequently in the EUS fibrosis group than no fibrosis group (51.6% vs 10.4%, p<0.001). The Arch-shaped submucosal deformity was a significant independent predictive factor for presence of submucosal cancer invasion than Fan type or no SM deformity group (80.9% vs 18.2% vs 19.5% odds ratio 11.83) (p<0.001). With regard to the results of endoscopic resection, curative, and complete resection rate were significantly lower in EGCs with the antrum submucosal deformity than those with no SM change or fan-type SM change groups (p<0.001).

Conclusion: Pattern analysis of the submucosal deformity on EUS examinations can be an useful tool for predicting the presence of the histologic ulcers and cancer invasion in ulcerative EGC.

Introduction: Endoscopic submucosal dissection (ESD) is an accepted curative treatment option for gastric tumors with very low local recurrence. However, residual or locally recurrent tumors occur rarely after ESD. Although secondary (Redo) ESD is technically demanding, it can be applied to residual or recurrent tumors that were treated by submucosus. Here, we investigated the feasibility and safety of secondary ESD for gastric tumors.

Aims and Methods: Between 2010 and 2017, 1623 consecutive patients underwent ESD for gastric neoplasms at a single tertiary referral center. Among these, 28 patients underwent secondary ESD for a residual or locally recurrent tumor. Our analysis compared clinopathologic factors between primary ESD and secondary ESD groups.

Results: The en-bloc resection and curative rate of resection of secondary ESD were 92.9% and 89.3%, respectively. The average procedure time of secondary ESD was significantly longer than primary ESD (78.2 vs. 55.1 minutes, p=0.004) and the adverse events rate was slightly higher in secondary ESD group than primary ESD group without statistical significance (10.7 vs 3.8%, p=0.095).
Patients who received secondary ESD had favorable outcomes without severe adverse events during follow-up period, no local recurrence occurred in patients who received secondary ESD.

Conclusion: Although it requires greater technical efficiency and a longer procedure time, secondary ESD of residual or locally recurrent gastric tumors appears to be a feasible and curative treatment.

P054 RISK FACTORS FOR EARLY AND DELAYED POST-OPERATIVE BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION OF GASTRIC NEOPLASMS

St. Marianna University. School of Medicine, Gastroenterology and Hepatology, Kawasaki, Japan

Contact E-Mail Address: ynakamoto@marianna-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) has become widely accepted as a standard treatment for gastric neoplasms. The safety of gastric ESD has been mostly established, although complication such post-operative bleeding and perforation remain problematic.

Since 2012, an endoscopic approach involving continued administration of low-dose aspirin (LDA) for patients at high risk of thromboembolism has been recommended in Japan. This approach is similar to the one stated in the guidelines of the European Society of Gastrointestinal Endoscopy; however, there is an insufficient date to support this guideline in Japan.

Aims and Methods: The aim of this study was to identify risk factors for early and delayed post-operative bleeding after gastric ESD and to evaluate the relationship between the use of antithrombotic agents and post-operative bleeding.

From January 2004 to December 2017, we analyzed 922 patients (673 men and 249 women, mean age 72.7±14.4years) 961 gastric neoplasms who treated by ESD at our hospital. Traditionally, we have interrupted therapy 5-7 days before gastric ESD for patients using LDA. However, since January 2012, we have followed the above mentioned guidelines, thus performing ESD with continued LDA for patients at high risk of thromboembolism.

In this study, post-operative bleeding was defined as a decrease in the blood hemoglobin level of ≥ 2g/dL accompanied by an occurrence of hematemesis or melena.

Bleeding within 6 days after ESD was defined as early post-operative bleeding, whereas bleeding on the sixth day or later post-operatively was defined as delayed post-operative bleeding.

Risk factors for early and delayed post-operative bleeding were retrospectively examined using univariate and multivariate analysis.

Results: The overall post-operative bleeding rate was 4.4%. The mean duration until post-operative bleeding was 2.4±6.4days. The post-operative bleeding rate for patients who continued LDA, discontinued antithrombotic agents, or received heparin replacement (HR) were 11.1%, 5.5%, and 13.1%, respectively. In the multivariate analysis, chronic kidney disease (CKD) requiring hemodialysis (p = 0.005; odds ratio 6.71, 95% CI 1.79-25.1), HR (p <0.01; odds ratio 4.15, 95% CI 1.73-9.93) and a specimen size of ≥ 50mm (p = 0.024; odds ratio 2.27, 95% CI 1.11-4.62) were independent risk factors for post-operative bleeding.

Delayed post-operative bleeding rate was 2.5%. In the multivariate analysis, HR (p <0.002; odds ratio 5.69, 95% CI 1.92-116.8) was independent risk factor for delayed post-operative bleeding.

Conclusion: Continued LDA was not risk factor for post-ESD bleeding. CKD requiring hemodialysis, and HR ≥ 50mm were independent risk factors for early post-operative bleeding, whereas HR is an independent risk factor for delayed post-operative bleeding. The timing of post-operative bleeding differs with the factors. Careful observation is required for patients at high risk of post-operative bleeding.

Disclosure: Nothing to disclose.

P0543 A NEW HISTOPATHOLOGICAL CLASSIFICATION OF GASTRIC ADENOCARCINOMA OF FUNDIC GLAND MUCOSAL TYPE AND CLINICOPATHOLOGICAL FEATURES OF GASTRIC ADENOCARCINOMA OF FUNDIC GLAND MUCOSAL TYPE (A MULTICENTER STUDY OF 80 CASES)

Introduction: Gastric adenocarcinoma of fundic gland type (GAFG) is newly added as a special type cancer in Japanese classification of gastric carcinoma, the 15th Edition 1). GAFG is an uncommon variant of gastric adenocarcinoma which has a distinct clinicopathological, immunohistochemical, and endoscopic features 2-4). GAFG is defined by positive immunohistochemical staining for pepsinogen-I (a marker of chief cells) and H+K+-ATPase (a marker of parietal cells) and is not associated with H. pylori infection. We suggested that a progression of GAFG might be associated with GNAS mutations 5).

Histopathologically, GAFG is classified into pure GAFG and gastric adenocarcinoma of fundic gland mucosal type (GAFGM) which exhibited differentiation toward gastric foveolar epithelium in addition to fundic gland differentiation. However, the histopathological classification of GAFG including GAFGM have not been well investigated.

Aims and Methods: The aim of this study was to establish a new histopathological classification of GAFG and clarify the clinicopathological features of GAFGM by comparisons with pure GAFG. A total of 80 GAFG cases from April 2004 to December 2017 were retrospectively collected from 27 institutions. We performed an immunohistochemical analysis using pepsinogen-I, H+K+-ATPase, MUC5AC (a marker of foveolar epithelial cells) and MUC6 (a marker of mucus neck cells) to classify these GAFG cases as pure GAFG, MUC5AC+/-MUC6+/- (p <0.01) and GAFGM (MUC5AC+, >10% MUC6+/- pepsinogen-I and/or H+K+-ATPase+, n = 57) or GAFGM (MUC5AC+, >10% MUC6+/- pepsinogen-I and/or H+K+-ATPase+, n = 23). In addition, GAFGM was classified to 3 subtypes, as follows;

Type 1. Tissue construct of foveolar epithelium and fundic gland is maintained, and tumor is exposed on the surface (n=9), Type 2. Tissue construct of foveolar epithelium and fundic gland is collapsed, and tumor is exposed on the surface (n=10), Type 3. Tissue construct of foveolar epithelium and fundic gland is collapsed, and tumor is not exposed on the surface (n=20). We then compared the pure GAFG and GAFGM cases, and 3 subtypes of GAFGM via a clinicopathological analysis and the frequency of GNAS mutation.

Results: There were no significant differences between the 2 groups (pure GAFGs vs. GAFGMs) in the following findings: location of lesion, macroscopic type, method of treatment, depth of invasion, lymph node metastasis, proliferative activity, p53 protein overexpression, H. pylori infection, and activating mutations in GNAS (p = 0.006; odds ratio 3.96, 95% CI 1.30-12.0), and a specimen size of 50 mm (p = 0.024; odds ratio 0.71, 95% CI 0.30-1.69). There were no significant differences between pure GAFG and GAFGM cases, and 3 subtypes of GAFGM in pepsinogen-I, H+K+-ATPase, MUC5AC, MUC6, and p53 protein overexpression.

Conclusions: The histopathological classification of GAFG is useful to estimate its clinicopathological differences, and should be categorized as a new aggressive variant of GAFG that has high malignant potential and differ in malignancy by tissue construct of foveolar epithelium and fundic gland.

Disclosure: Nothing to disclose.

References
diagnosis, for male sex 2.0-fold, G3 according to mitosis count 3.0-fold, G3 according to ki67, tumor stage 3 or 4 cases 12.7-fold, 1 cm increase in tumor size 9%, liver metastasis 6.1-fold, by every 1 mg/dl increase in CRP level 1.5%. There was a significant difference between the pancreas and stomach NETs in favor of stomach tumors in terms of survival.

Conclusion: As a result, it was observed that 1 of the biochemical parameters, CRP affected the course of the progression in the worst way (particularly if it is > 20 mg / dl). With the need for larger scale and prospective studies, it was suggested that CRP level might be a poor prognostic factor for the entire GEP-NET group.

**Introduction:** Indications for endoscopic submucosal dissection (ESD) of early gastric cancer (EGC) are expanding, but signet ring cell (SRC) carcinoma is still unclear because of its unclear lateral margin.

**Aims and Methods:** The purpose of this study was to compare pathologic size and endoscopic size in early gastric SRC and to find risk factors associated with tumor size underestimation. A retrospectively medical records reviewed of total 137 patients with diagnosed early gastric SRC between January 2009 and December 2016 at our tertiary hospital. According to pathologic and endoscopic tumor sizes, classified into correct estimation, underestimation and overestimation groups, and risk factors related to underestimation were analyzed.

**Results:** Among 137 patients with early gastric SRC, 77 patients (56.2%) had undercorrected estimation, 43 patients (31.4%) had underestimation and 17 patients (12.4%) had overestimation. Mean pathologic size was SD (20.1 (13.8) mm and mean endoscopic size (SD) was 17.9 (10.1) mm, the correlation coefficients were 0.919 (p = 0.000) and there was no significant difference between the two groups. Multivariate analysis showed that more than 20mm endoscopic tumor size (OR, 3.419; 95% CI, 1.271–9.194, p = 0.015) and atrophy (OR, 6.011; 95% CI, 2.311–15.633, p < 0.001) was a risk factor for tumor size underestimation.

**Conclusion:** There was no significant difference in pathologic and endoscopic size in early gastric SRC. Therefore ESD may be considered as a therapeutic option if the size of the tumor is less than 20 mm and atrophy is not present in the surrounding mucosa.

Introduction: Synchronous gastric neoplasms is the major concern after endoscopic resection (ER) for early gastric cancer (EGC). Several studies showed that patients with EGC with synchronous neoplasm had increased recurrence rate after ER than those with single EGC. However, the incidence and prognosis are not well-known in patients with synchronous neoplasm including adenoma.

**Aims and Methods:** In this study, we compared the outcome between patients with single neoplasm and synchronous neoplasm including adenoma after ER. We also compared the outcomes of synchronous neoplasm subgroup which were divided according to the diagnostic histology.

A total of 1569 patients who underwent ER for gastric neoplasm were divided according to the diagnostic histology. Patients were determined by electrochemiluminescence assay (Roche cobas e 601, Switzerland).

**Results:** Among 137 patients with early gastric SRC, 77 patients (56.2%) had undercorrected estimation, 43 patients (31.4%) had underestimation and 17 patients (12.4%) had overestimation. Mean pathologic size was SD (20.1 (13.8) mm and mean endoscopic size (SD) was 17.9 (10.1) mm, the correlation coefficients were 0.919 (p = 0.000) and there was no significant difference between the two groups. Multivariate analysis showed that more than 20mm endoscopic tumor size (OR, 3.419; 95% CI, 1.271–9.194, p = 0.015) and atrophy (OR, 6.011; 95% CI, 2.311–15.633, p = 0.001) was a risk factor for tumor size underestimation.

**Conclusion:** There was no significant difference in pathologic and endoscopic size in early gastric SRC. Therefore ESD may be considered as a therapeutic option if the size of the tumor is less than 20 mm and atrophy is not present in the surrounding mucosa.

**Introduction:** The phenomenon of active inflammatory crosstalk between tumor cells and the surrounding stroma has attracted more and more attention [1]. Some investigations have indicated that inflammation-related proteins, such as matrix metalloproteinase (MMPs), may facilitate the growth, proliferation, and migration of tumor cells, including GC [2–4]. This study was carried out to reveal and testify their significance as candidates for tumor markers of GC.

**Aims and Methods:** Plasma samples from 12 GC patients (3 cases for each clinical stage from I to IV) and 10 non-neoplastic gastric disease (NGD) patients (3 cases with chronic superficial gastritis, 4 cases with chronic atrophic gastritis or intestinal metaplasia and 3 cases with dysplasia) were collected from November 2016 to March 2017 as training set. Human MMP arrays (RayBiotech, Norcross, GA, USA) were used to quantitative measurement of 7 major MMPs (MMP-1, MMP-2, MMP-3 MMP-8, MMP-9, MMP-10, and MMP-13) and 3 other endo- genous inhibitors (TIMP-1, TIMP-2, and TIMP-4) simultaneously. Then the levels of them were compared between the GC and NGD groups and their diagnostic value was assessed by ROC curve. The candidate differential subtypes were validated by corresponding serum microchips in another group of patients, which included 40 GC patients and 38 NGD patients. Additionally, the levels of CRP and CA19-9 were also assayed in the GC group, the CA19-9 level in synchronous group was 125 (CA125), and carbohydrate antigen 19-9 (CA19-9) in plasma of the 52 GC patients were determined by electrochemiluminescence assay (Roche cobas e 601, Switzerland).

**Results:** Compared to the NGD group, except MMP-2, MMP-3 and MMP-13, other MMPs showed an increased trend in the GC group, but no significant difference in the training set. Only TIMP-4 increased significantly in the GC group compared to the NGD group, p < 0.05. The area under the curve (AUC) of the MMPs were from 0.500 to 0.858, and combined AUC of them was 0.858 (95% CI, 0.699-1.000) for the diagnosis of GC. Particularly, TIMP-4, whose AUC was the highest, 0.858 (95% CI: 0.692-1.000). At the optimal cut-off value of 2438.3 pg/ml, its sensitivity, specificity and accuracy for the diagnosis of GC were 83.5%, 80.0% and 81.8%, respectively. In the validation set, the concentration of TIMP-4 in GC and NGD group were 1101.2 2.703.3 pg/ml and 890.1 1.457.4 pg/ml, respectively. Compared with the NGD group, the concentration of TIMP-4 increased in the GC group, but no statistical difference was found. Its AUC value for the diagnosis of GC was 0.574 (95% CI: 0.444-0.704). Furthermore, the positive rates of AFP, CEA, CA125 and CA19-9 in both sets for the diagnosis of GC and early gastric cancer (EGC), as shown in Table 1. **Conclusion:** The diagnostic value of the candidate tumor markers is limited. However, MMP profiles may have potential value for the diagnosis and screening of GC. TIMP-4 is a promising biomarker for the auxiliary diagnosis of GC.

Clinical Course After Non-Curative Endoscopic Submucosal Dissection for Early Gastric Cancer Without Additional Surgery

T Shimada, Y Yamagata, T Ohira, Y Harada, Y Kanno, Y Kioke, M Tanaka, K Ito
Sendai City Medical Center Dept. of Gastroenterology, Sendai, Japan

Introduction:
Early gastric cancer (EGC) is not curatively treated by endoscopic submucosal dissection (ESD), additional surgical gastrectomy is not performed for various reasons.
